ACKNOWLEDGMENTS

Thanks to the many individuals who have participated in the field collections, often under difficult and arduous circumstances, especially Captains Deane Estes, Wendy Lowery and Hank Brooks and the rest of the scientific and technical staff including Aimee Halvorson, Amanda Hewitt, Julia Ellis, Courtney Ford, Colleen Newberg and Pat McGrath. Appreciation is expressed to Chris Bonzek for data management assistance and Julia Ellis for table and graphics preparation.

A special thanks to those marinas which provided monthly mooring facilities for the *R/V Fish Hawk* throughout the state. These include Sunset Marina and Kingsmill Marina on the James River/Hampton Roads and Norview Marina on the Rappahannock River.

This project was supported by Virginia Marine Resources Commission Marine Recreational Fishing Advisory Board, Project No. RF 05-15.

DISCLAIMER

Some of the results contained in this report have recently been completed and may contain some errors and/or need further refinement. In particular, information pertaining to gear conversions and the longer time series they provide (1955-2005) should be used with some caution until further evaluation.

EXECUTIVE SUMMARY

The fisheries trawl survey conducted by the Virginia Institute of Marine Science (VIMS) is the oldest continuing monitoring program (50 years) for marine and estuarine fishes in the United States. This survey provides a monthly baseline assessment of abundance of juvenile marine and estuarine fishes and crustaceans in the tidal and mainstem Chesapeake Bay. The survey provides crucial, real time data to various state, regional and national fisheries management agencies, including the Virginia Marine Resources Commission (VMRC), the Atlantic States Marine Fisheries Commission (ASMFC), the Mid-Atlantic Fisheries Management Council (MAFMC), and the National Marine Fisheries Service (NMFS). For example, the VIMS Trawl Survey provided the ASMFC with the only spot index available on the East Coast and was the cornerstone for the 2003 ASMFC Spot FMP. The MAFMC recognizes the VIMS Trawl Survey as the only available predictor of summer flounder recruitment and recently the American eel index was vital to the 2006 ASMFC American Eel management Plan.

In the Virginia portion of Chesapeake Bay, several annual indices of juvenile abundance have been generated from trawl survey data for species of key recreational, ecological, and commercial importance. These include spot, Atlantic croaker, weakfish, summer flounder, black sea bass, scup, striped bass, white perch, white catfish, channel catfish, blue catfish, northern puffer, silver perch, blue crab, American eel, bay anchovy and Atlantic menhaden.

Historically four different estimates of relative abundance have been developed for juvenile finfish in the survey. However, only the converted indices (random stratified converted index - RSCI) and unconverted indices (random stratified index - RSI) for the target species discussed are the focus of this report.

In recent years, juvenile indices for most species have declined, most often a result of overfishing, degradation of their estuarine nursery habitats, and year class failure due to natural environmental variation. For example, spot RSCI indices have declined greatly over the past 50 years, with their 1955-1978 index twice the 1979-2005 index. Croaker show the greatest interannual variability of the key species discussed, with fluctuations most probably weather related. There was an increasing trend in weakfish converted indices since 1994, while summer flounder have remained low, most probably due to overfishing and year class failure, which were revealed in the very low 1987 trawl index. The 2005 black sea bass index is the lowest since 1968. The scup index has been highly variable and increased slightly in 2004. Striped bass indices were very low during the 1970's and early 1980's, rebounded in the early 1990's and have decreased and remained low since 2001. White perch YOY and age 1+ indices increased slightly in 2005 from the previous year. The white catfish YOY index decreased in 2005 and the white catfish age 1+ index increased slightly. The channel catfish YOY and age 1+ index decreased in 2005. Both blue catfish indices (YOY and age 1+) have increased since 2001. Since 1988, northern puffer indices experienced a rapid and continuous decline. The silver perch index has remained consistently low since 1972. Both age 1+ and adult female blue crab indices exhibited significant declines. Both American eel and bay anchovy indices have decreased since the early 1980's. The newly created Atlantic menhaden index decreased in 2006. The Chesapeake Bay is a major nursery area for many coastal migratory fish species and an integral part of multistate management efforts along the Atlantic Coast of the United States.

INTRODUCTION

A key element in the management of the Atlantic States' coastal fishery resources is the use of juvenile abundance estimates (indices) of important finfish and invertebrates. Relative interannual abundance estimates of early juvenile (age 0) fish (i.e. striped bass, *Morone saxatalis*) and crustaceans (i.e., blue crab, *Callinectes sapidus*) generated from scientific (fishery-independent) survey programs provide a reliable and early estimator of future year class strength (Goodyear, 1985; Lipcius and Van Engel, 1990), and may be used to validate management actions. The Chesapeake Bay Stock Assessment Committee (CBSAC), a federal/state committee sponsored and funded by the National Oceanic and Atmospheric Administration (NOAA) reviewed previously available indices of juvenile abundance for important fishery resource species in the Chesapeake Bay (hereafter referred to as "Bay") and recommended that "a unified, consistent trawl program should be one of the primary monitoring tools for finfish and crab stock assessment" (Chesapeake Bay Program Stock Assessment Plan, Chesapeake Executive Council, 1988). Subsequently, CBSAC supported pilot studies directed at developing a comprehensive trawl survey for Chesapeake Bay. The primary focus of this support in the Virginia portion of the Bay was the initiation (1988) of a monthly trawl survey of the mainstem lower Bay. This effort complimented and expanded the monthly trawl surveys of the major Virginia tributaries (James, York and Rappahannock Rivers), which had been conducted by the Virginia Institute of Marine Science (VIMS) as part of a long-term monitoring effort to assess the condition of fishery stocks in the lower Chesapeake Bay and its tributaries.

The present sampling program, which includes the Bay and its tributaries, is vital in insuring that data are of sufficient geographic resolution for the generation of annual indices of recreationally, ecologically and commercially important finfish and crustaceans. The National

Marine Fisheries Service (NMFS) Marine Recreational Fisheries Statistics Survey (MRFSS) 2004 survey for Virginia marine recreational catches were dominated by Atlantic croaker (*Micropogonias undulatus*), summer flounder flounder (*Paralichthys dentatus*), spot (*Leiostomus xanthurus*), striped bass (*Morone saxatilis*), black sea bass (*Centropristes striata*), bluefish (*Pomatomus saltatrix*), pigfish (*Orthopristis chrysoptera*), weakfish (*Cynoscion regalis*), and kingfishes (*Menticirrhus* spp.; Anon., 2004; see Table 1). These are the top species landed by catch (89% of the total catch) and weight (84% of the total weight; Table 1). These species depend upon the lower Chesapeake Bay and its tributaries as a nursery area, with all but bluefish highly vulnerable to bottom trawls. In addition to the key species above, past survey results indicate other species of recreational interest, including scup (*Stenotomus chrysops*), white perch (*Morone americana*), silver perch (*Bairdiella chrysoura*), white catfish (*Ictalurus catus*), channel catfish (*I. punctatus*) and blue catfish (*I. furcatus*), are taken with sufficient regularity during trawling operations to provide datasets suitable for the generation of juvenile abundance indices. Although generation of annual juvenile (young-of-year or YOY) indices is the primary focus of this project, survey results can be used to address other aspects of finfish population biology, such as habitat utilization, early growth and survival, climate and pollutant interactions, or disease prevalence. For example, climate effects such as hurricanes affect recruitment of shelf spawning species such as Atlantic croaker (Montane and Austin, 2005). The development of juvenile indices requires a continuous time series of data to determine the proper area-time sequences best used in index calculations. Provisional annual juvenile abundance indices were developed for spot, weakfish, Atlantic croaker, summer flounder, and black sea bass (Colvocoresses and Geer, 1991), followed by scup (Colvocoresses et al., 1992), and then white perch and striped bass (Geer et al., 1994). Indices for white catfish, channel catfish, silver perch

and northern puffer (*Sphoeroides maculatus*) followed (Geer and Austin, 1994). Blue catfish, blue crab, American eel (*Anguilla rostrata*), bay anchovy (*Anchoa mitchelli*) and Atlantic menhaden (*Brevoortia tyrannus*) indices have been recently developed also. A time series back to 1955 with the use of gear conversions and post stratification has also been produced for most species (Geer and Austin, 1997).

Many species of interest are captured in significant numbers across several year classes. As a result, both YOY and age 1+ indices were created for white perch, white catfish, channel catfish, blue catfish and blue crabs. For Atlantic croaker, in addition to a Fall YOY index, a recruit or Spring index (returning YOY) was created.

METHODS

Field Sampling

Sampling protocol is described in detail in Lowery et al., (2000). In brief, a lined 30' (9.14m) semi-balloon otter trawl, with 1.5" (38.1mm) stretched mesh and 0.25" (6.35mm) cod liner, is towed along the bottom for five minutes during daylight hours.

Sampling in the Bay occurs monthly except during January and March, when few target species are available. Sampling in the tributaries also occurs monthly, at both the random stratified stations and the historical fixed mid-channel stations. The stratification system is based on depth and latitudinal regions in the Bay, or depth and longitudinal regions in the rivers. Each Bay region is 15 latitudinal miles and consists of six strata; western and eastern shore shallow (4-12 ft.), western and eastern shoal (12-30 ft.), central plain (30- 42 ft.), and deep channel (\geq 42 ft.)(Table 2). Each tributary is divided into four regions of approximately ten longitudinal miles, with four depth strata in each (4-12 ft., 12-30 ft., 30-42 ft., and \geq 42 ft.) (Tables 3 - 5; Figure 1).

Strata are collapsed in areas where certain depths are limited. The fixed stations have been assigned a stratum according to their location and depth.

Due to funding restrictions, exploratory monitoring of secondary water systems (Pocomoke Sound, Mobjack Bay, Piankatank and Great Wicomico Rivers) which began in 1998, was discontinued in 2001. Each system was sampled quarterly, with a rotation to assure that over a three year period, each system would have sampling events during different times of the year. A random stratified design (RSD) similar to the primary survey was used. When compared to the mainstem Bay, James, York and Rappahannock Rivers, some of these systems have shown higher catch rates of summer flounder, spot and silver perch (Geer and Austin, 2000).

With the exception of the fixed river stations, trawling sites within strata are selected randomly from the National Ocean Service's Chesapeake Bay bathymetric grid, a database containing depth records measured or calculated at 15 cartographic second intervals. Two to four trawling sites are randomly selected for each Bay strata per month, the number chosen varying seasonally according to observed changes in distribution, with sampling intensity being highest in the most heavily utilized strata. Exceptions include the shallow water strata where one to two stations have been occupied for each month's survey. For each river strata, one to two stations are selected per month. The number of potential sites for the RSD of the Bay and tributaries with the approximate areas of each strata, are shown in Tables 2 - 5. The RSD of the York River which began in June 1991, has been altered slightly to make depth strata similar to the James, Rappahannock, and mainstem Bay. Earlier investigations (Geer et al., 1994) proposed that for the tributaries, all depths \geq 30 ft. be included in one stratum, and this was modified in January 1996, to create depth strata of 30-42 ft. and \geq 42 ft. (Geer and Austin,

1996a). Since these random stratified tributary data were considered conditional until all three tributaries were sampled (March 1996), previous samples were assigned to the appropriate strata established January 1996.

Earlier reports listed results dating back to only 1979 due to gear and sampling changes. With gear and vessel conversions now available for most target species, indices can be calculated for the pre-1979 data. Survey stations before 1979 have also been post-stratified to the present sampling scheme. Although the stratification of the mainstem Bay has not changed, that of the initial random stratified surveys of the rivers has.

The fixed channel sites on the tributaries are spaced at approximately 5 mile intervals from the river mouths up to nearly the freshwater interface. The fixed stations have been sampled monthly (nearly continuously) since 1980. From the mid-1950's (York River) and early-1960's (James and Rappahannock Rivers) to 1972, the fixed stations were sampled monthly using an unlined 30' trawl (Gear U_N_3B_SW, gear code 010). During 1973-79, semi-annual random stratified sampling was performed by the VIMS Ichthyology Department while the VIMS Crustaceology Department continued monitoring the fixed tributary stations on a limited monthly basis (May - November). Areal weightings for the tributaries have been previously assigned by dividing each river into two approximately equal length "strata" by assuming that the stations in each strata are representative of the channel areas in those reaches (Table 6; see also Lowery and Geer, 2000). With all three tributaries now being sampled with a random stratified design, the fixed stations have been assigned to a stratum based on location and depth. The present tributary survey (combining fixed and random stations) provides larger spatial coverage, a long-term historical reference, and is more statistically sound.

Beginning May 1998, data were collected on habitat or substrate type (Table 7). Fish distribution and abundance may be influenced by various substrates such as shell, sponge, hydroids, and sea squirts. Three dimensional structure may be used by different species for spawning, shelter, or feeding. Categories of substrates are measured at each trawling site based upon the quantity (volume in a standard container) observed in the net. Maps of substrate distribution can be developed and compared to catch rates and fish species distribution. Gelatinous zooplankton volumetric measurements are also collected at each trawl station.

Gear Calibration Studies

Gear calibration analyses were completed and methods and statistical analyses applied (Hata, 1997). Conversion values were applied to the historical data sets providing a converted catch for each observation, in most cases extending the individual species time series back to 1955.

Juvenile Index Computations

Many key target species of this study are migratory and abundance measurement presents special difficulties, particularly if the timing and duration of migration varies from year to year. Juvenile fishes which use estuarine nursery areas are especially vulnerable to the vagaries of climate, as many rely upon climatically dependent wind driven and tidal circulation patterns for semi-passive transport into the estuaries as larvae and early juveniles (Norcross, 1983; Bodolus, 1994; Wood, 2000) and later key their outward migration from the nursery areas on annually variable environmental cues (e.g. temperature changes). Ideally the abundance of a juvenile marine species population should be measured at that point when it is most fully recruited to the nursery area being monitored. However, in practice, this can only be accomplished if the time of maximal abundance and size of recruitment to the gear can be predicted (and surveys timed

accordingly), or if surveys can be conducted on such an intense periodicity over the season of potential maximal abundance as to be certain of reasonable temporal coincidence. Neither of these two approaches is practical for this survey. The period of recruitable maximal abundance and the scope of the area being surveyed has proven to be variable between years and species. This, coupled with multi-specific monitoring objectives precludes temporally intense surveys with finite resources. The multispecies nature of this program, also makes survey timing difficult to adjust in order to maximize the usefulness of the data to include all species. Consequently, the survey continues to be conducted on a regular periodicity and juvenile indices constructed as best possible.

Juvenile index calculation uses the following approach. A standard monthly cutoff value is applied to the length frequency information collected for each target species to separate the data into either young-of-year or older components. Cutoff values vary among months for each species and are based on modal analyses of historical composite monthly length frequency data and reviews of ageing studies for each species (Colvocoresses and Geer, 1991). For the earlier months of the biological year, cutoff values are usually arbitrary and fall between completely discrete modal size ranges. In the latter part of the biological year, when early spawned, rapidly growing individuals of the most recent year class may overtake late spawned, and slowly growing individuals of the previous year class, cutoff values were selected to preserve the correct numeric proportionality between year classes despite the misclassification of individuals (Table 8). The extent of the zone of overlapping lengths and the proportion within that range attributable to each year class is estimated based on the shapes of each modal curve during the months prior to the occurrence of overlap. A length value is then selected from within that range which will result in the appropriate proportional separation. Although this process involves

considerable subjectivity and ignores possible interannual variability in average growth rates, the likelihood of significant error is small, since only a very small fraction of the total number of young-of-year individuals fall within the zone of overlap and most of the data used to construct juvenile indices is drawn from months when no overlap is present. Furthermore, any error should be constant from year to year. Fish length was recorded as fork length (FL), total length (TL), or total length centerline (TLC) depending on individual species meristics.

After partitioning out non young-of-year individuals, monthly catch rates of target species are map-plotted and strata-specific abundances and occurrence rates calculated. Numbers of individuals caught are logarithmically transformed ($\ln(n+1)$) prior to abundance calculations, since the log transform best normalizes collection data for contiguously distributed organisms such as fishes (Taylor, 1953) and has been verified as the best suited transformation for Chesapeake Bay trawl collections (Chittenden, 1991). Resultant average catch rates (and the 95% confidence intervals as estimated by ± 2 standard errors) are then back-transformed to the geometric means. Coefficient of variation is expressed as the log transformed mean catch, EY_{st} divided by the standard deviation, EY_{st} / STD (Cochran, 1977). Plots and data matrices are then examined for area-time combinations which provide the best basis for juvenile index calculations. Criteria applied during the selection process include identification of maximal abundance levels, uniformity of distribution, minimization of overall variance, and avoidance of periods in which distribution patterns indicate migratory behavior is occurring. Although identification of areas most suitable for index calculations (primary nursery zones) is generally clear, selection of appropriate time windows is more complex. Surveys are timed on regular monthly intervals which may or may not coincide with periods of maximal recruitment to the nursery areas. The use of a single (maximal) month's survey results is inappropriate, since using

a very limited portion of the overall dataset would decrease sample size, increase confidence intervals, and increase the risk of sampling artifacts. Conversely, the temporal series of data incorporated into index calculations should not be longer than necessary to capture the period of maximal juvenile utilization of the nursery area, since indices calculated over longer time periods risk confounding temporal persistence on the nursery area with maximal utilization levels. With this approach, we can identify three or four month periods which provide realistic abundance data for the species examined (Table 8).

After area-time combinations are selected, annual juvenile indices are calculated as weighted geometric mean catch per tow. Strata-specific means and variances are calculated and then combined and weighed by stratum areas (Cochran, 1977). Since stratum areas are quite variable, a weighted mean provides an index that more closely mirrors actual population sizes.

The following indices are produced for each species, if appropriate: the original index based on the present Bay strata and the fixed mid-channel tributary stations (Bay & River Index - BRI and River Only - RO, 1979 to present); a post-stratified gear and/or vessel converted index using all spatially appropriate data (Random Stratified Converted Index - RSCI, 1955 to present); and an unconverted post-stratified index, also based on all spatially appropriate data (Random Stratified Index - RSI, 1955 to present). These multiple indices are presented for completeness, but usually only the RSCI (or RSI) will be described in detail in this report. Results from the longer time series must be considered provisional, since concerns about missing data and conversion factors are continually being addressed. Index regressions were conducted with year as the independent variable and species index as the dependent variable to exhibit trends over time. However, fishery dependent time series data, as with any time series data with successive observations, are usually not independent and are often autocorrelated (Chatfield, 1994). For

each index, a t-test of the slope coefficient (from the regression) will be reported, if significant ($P < 0.05$).

Monthly size frequencies for selected species are included in the report as they indicate when a species first recruits to the survey gear. Additionally, in collaboration with the Chesapeake Bay Trophic Interaction Laboratory at VIMS, Atlantic croaker, weakfish, blue catfish, striped bass, summer flounder and silver perch were collected from the James, York and Rappahannock Rivers for stomach analyses (see Parthreee et al., 2006) and blue catfish prey items are discussed briefly. Though this project produces indices for multiple species, we are only beginning to investigate multispecies interactions in an effort to better understand the Chesapeake Bay fishery ecosystem and report on interactions between the catfishes. The VIMS Trawl Survey also plays an important role responding to numerous advisory service requests (for examples, see Appendix Table 1).

RESULTS

Our objective was to develop and produce timely annual estimates of recruitment for important finfish and crustaceans for the major Virginia nursery areas of Chesapeake Bay. A summary of samples collected from 1955 through May 2006 (Table 9) gives a brief synopsis of the sampling conducted since the start of the survey. For the 2005-2006 project year (June through May), 1211 stations were sampled, resulting in approximately 417,000 fishes and invertebrates identified and enumerated from 105 species collected (Table 10). The overall catch was dominated by bay anchovy and spot (Table 10).

Indices were calculated and described for the following species: spot, Atlantic croaker, weakfish, summer flounder, black sea bass, scup, striped bass, white perch, white catfish,

channel catfish, blue catfish, northern puffer, silver perch, blue crab, American eel, bay anchovy and Atlantic menhaden. For each species, detailed analyses and spatial distribution plots follow. VIMS Trawl Survey indices are also available on the survey website at <http://www.fisheries.vims.edu/trawlseine/mainpage.htm>.

Spot (*L. xanthurus*) - Spot has often been the most abundant of the recreational species caught by the survey, however in recent years their numbers have declined. Their distribution is wide and consistent throughout the sampling area (Figure 4, bottom). Juveniles can initially recruit to the gear as early as April, but during this survey period, their abundance peaked between July through November 2005 (Figure 5). The RSCI index (1955-2005) for spot exhibited a significant negative slope when regressed against year ($t = -2.72$, $df = 1$, $P < 0.05$, see Table 11 and Figure 4, top). The spot RSCI index has fluctuated over the fifty year time series and a dramatic and consistent decline is evident from 1992 to the present (Figure 4, top).

Atlantic Croaker (*M. undulatus*). Croaker display high abundance in the survey catches and are distributed throughout the survey area (Figure 6, top and bottom). Spawning takes place over a more protracted period than other species considered, and small early juveniles (<30 mm TL) can be present in catches year-round (Norcross, 1983; Colvocoresses and Geer, 1991; Colvocoresses et al., 1992; Geer et al., 1994; 1995; Land et al., 1995). During some years, peak abundance occurs in the fall with croaker less than 100 mm TL, but in other years the peak occurs the following spring and includes croaker either overwintering or recruiting from offshore waters. To separate these size cohorts, two estimates are generated: a juvenile Fall (Oct. - Dec.) index based just on the tributaries; and a Spring recruit (May - Aug.) index (Bay and tributaries combined).

Successful spawning events are evident from the very successful year classes in the fall of 1984, 1985, 1989 and 2003 (Table 12, Figure 6, top). The spike in the Fall 2003 YOY croaker index was caused by Hurricane *Isabel* which struck Chesapeake Bay from 18-19 September (Montane and Austin, 2005), and produced prolonged onshore winds for many days prior (NOAA, 2003). The 2005 fall croaker index was less than the 2004 index and slightly lower than the fifty year mean (mean = 12.94; s.e. = 3.0) However, these successful spawning events often did not result in comparably successful recruitment the following spring (Table 13 and Figure 7, top and Figure 8). There was no significant relationship between the fall YOY and spring recruit indices.

The Fall YOY RSCI (1956-2005) and Spring Recruit RSCI (1955-2005) for croaker were analyzed for annual trends. The Fall YOY RSCI (1956-2005) exhibited a significant positive slope ($t = 2.65$, $df = 1$, $P < 0.05$; see Table 12 and Figure 6, top), while the spring recruit RSCI did not exhibit a trend (Table 13 and Figure 7). Newly recruited YOY Atlantic croaker were first captured by the survey gear in October 2005 (Figure 8).

Weakfish (*C. regalis*) - Weakfish are less abundant than spot and croaker, but are still one of the dominant species in the survey, and are found throughout the Bay and tributaries (Figure 9, bottom). Juveniles have occasionally first occurred in catches as early as late May and June, with June taken as the beginning of the biological year. During this project period, most new recruitment to the nursery areas occurred July through October 2005 with a majority of the smaller fish recruiting in September and October 2005 (Figure 10).

Weakfish indices have been highly variable, with a slight increasing trend from 1994 to the present in the RSCI index (Figure 9 top, Table 14). The most striking observation of the weakfish time series is the poor recruitment between 1972 and 1977 (which were years of high

precipitation in Chesapeake Bay), though before and after this period, there was successful recruitment in 1970 and 1978 (Figure 9, top and Table 14).

Summer Flounder (*P. dentatus*) – Summer flounder spawn during the offshore migration from late summer to midwinter (September through January) on the continental shelf with the peak occurring in October and November (Murdy et al., 1997; Able and Fahay, 1998). Flounder larvae enter the Bay and other Virginia estuaries from October through May with juveniles utilizing shallow fine substrate habitat adjacent to seagrass beds (Murdy et al., 1997; Norcross and Wyanski, 1994; Weinstein and Brooks, 1983; Wyanski, 1990). Low water temperatures can have significant effects on early demersal individuals that enter the estuary in the winter (Able and Fahay, 1998). Juvenile summer flounder can first appear in catches as early as late March, which is used as the beginning of the biological year. YOY summer flounder abundance continues to increase steadily throughout the summer and early fall to a late fall peak, and then shows evidence of emigration during December. September, October, and November usually encompass the three months of greatest abundance. Historically during this period, juvenile flounder are broadly distributed across the mainstem Bay and are found in the lower rivers, but only rarely appear in catches in the upper rivers. Index calculations therefore include all Bay and the lower river strata during these three months. During this project period, flounder were sparse in the upper Rappahannock River and bay mainstem (Figure 11, bottom). .

The summer flounder RSCI (1955-2005) did not exhibit an annual trend over the fifty year period (Table 15). Annual RSCI index values were high in 1980 and 1983, and 2005 was the lowest flounder index since 1975. Minor peaks occurred in the early nineties (1990, 1991 and 1994), but the last few years have been consistently low. Small YOY flounder first appeared in June 2005 (Figure 12).

Black Sea Bass (*C. striata*) - Black sea bass are seldom taken in large numbers but regularly occur in survey catches. When present, young-of-year black sea bass occur throughout the Bay strata but rarely appear in the tributaries except possibly the lower James River (Figure 13, bottom). Index calculations have been based on all Bay strata and the lower James stratum from May through July. Although some early juveniles appear in the Bay during their first summer and fall and then emigrate with the onset of winter, more young-of-year enter the estuary during the following spring. Black sea bass spawn in the Mid Atlantic Bight beginning in April, peaking in August, and continuing through October (Murdy et al., 1997; Able and Fahay, 1998). However, during some years there is virtually no recruitment to the Chesapeake Bay by early juveniles spawned the same calendar year. Since this index is calculated from the middle portion of the calendar year but the very end of the biological year, the resultant index is for the year class spawned the previous calendar year (i.e., the 2004 index is for the 2003 year class). When the black sea bass RSCI (1954-2004) was analyzed for annual trends, the RSCI showed an increasing significant slope ($T = 2.17$, $df = 1$, $P < 0.05$, Figure 13, top; Table 16). The 2004 RSCI index was the lowest since 1968 (Figure 13, top).

Scup (*S. chrysops*) - Scup is primarily a marine and summer spawning species and utilizes the Chesapeake Bay the same as black sea bass. The estuary is rarely used as a nursery area by early juveniles but many older juveniles can be found there during their second summer. Early juvenile scup (25-40 mm FL) occasionally appear in survey catches in June, but usually rapidly disappear thereafter. Older scup first appear in catches in May, and by June range from 50 to 215 mm FL. The original length cutoff criteria were based on ageing studies (Morse, 1978), with the collective trawl data indicating three size or year classes (age 0, age 1 and age 2+). Since the age 0 is annually variable and not persistent, and the age 2+ is only taken in very

small numbers, index calculations are performed on age 1 individuals. This year class clearly remains present in the Bay and available to the gear for the remainder of the summer and early fall. While the data collected are not amenable to construction of a true YOY juvenile index, the abundance of juvenile scup just as they enter their second year can be assessed. The term, "age 1" scup was often used in earlier reports, when in actuality data were lagged one year (year - 1), referring to YOY measured in their second year. Although there has been some discussion whether animals captured in Chesapeake Bay are YOY or early age 1, based on studies along the Virginia coast, trawl catches in these size ranges represent mainly age 1 individuals (Campbell et al., unpublished manuscript).

The early age 1 nursery area is largely restricted to the two lower mainstem Bay segments (Figure 15, bottom). Catch rates for scup usually peak in July, and essentially show a July-August dome. Since sizable numbers of late juveniles have also been collected during June and September, these months were chosen as the temporal basis for index calculation.

A regression of scup RSCI index (1954-2004) vs. year did not exhibit a trend (Figure 15, top and Table 17). Scup indices have been consistently low since 1993, but showed a slight increase in 2004 compared to 2003. Most scup were collected from July through September 2005 (Figure 16).

Striped Bass (*M. saxatilis*) - Striped bass use the upper tributaries for spawning and nursery grounds, spawning from early to mid-April through the end of May, in tidal freshwater areas just above the salt wedge. YOY striped bass often appear in catches in May to July in size classes less than 50 mm FL during years of greater abundance, but then diminish in abundance until the following winter. A second, stronger, and more consistent period of abundance occurs in December and continues through to February the following year in the upper regions of the

rivers. YOY striped bass are found exclusively in the rivers (Figure 17, bottom). This is probably due to their local migration into deeper waters in colder weather.

When the striped bass RSCI (1956-2005) was analyzed for annual trends, there was a significant negative slope over time ($T = -3.49$, $df = 1$, $P < 0.05$; Figure 17, top and Table 18). However, the RSCI index has been highly variable since 1982, having very low abundances through the 1970's. There was a slight increase in the 2005 index compared to 2004. Index values are constructed with YOY collected from December through February. In Summer 2005, YOY spikes occurred in June and July (Figure 18).

White Perch (*M. americana*) - Spawning occurs in the upper tributaries from March to July with a peak occurring from late April to early May. Since white perch populations from various tributaries can exhibit significantly different growth rates (Bowen, 1987; Setzler-Hamilton, 1991a; Seaver et al., 1996), and those separations are not presently clear, for this analysis all specimens were categorized as either age 0 or age 1+. Examination of distributional data (Figures 19 and 21, bottom), reveals neither white perch cohort are found in the mainstem Bay, with the highest abundances found in upper portions of each tributary. Therefore, index calculations are confined to the upper strata of each tributary. Index months include December to February for YOY and November to February for age 1+, though periodically some age 1+ are caught in March, and YOY caught in other months as well (Figure 20).

The RSCI (1956-2005) indices for YOY showed no significant annual trends, while the age 1+ RSCI for the same period exhibited a significant negative slope over time ($t = -0.369$, $df = 1$, $P < 0.05$; Figures 19 and 21, top and Tables 19 and 20). The age 1+ RSCI index was fairly high from 1960-1964, and then decreased.

White catfish (*I. catus*) and **Channel catfish** (*I. punctatus*) - White catfish and channel catfish are usually found in the upper portions of the tributaries (Figures 22, 24, 25, and 27, bottom). Although each river system is unique, spawning typically occurs in late May through early July in Virginia (Fewlass, 1980; Menzel, 1945); consequently June was selected as the start of the biological year. The survey typically catches both species up to 600 mm FL with juveniles 50 mm FL first recruiting to the gear in June. In summer 2005, small white catfish appeared in September, and small channel catfish in November (Figures 23 and 26). In most years, the temporal component seems very clear for the juveniles occurring from January to April for both species in the upriver strata only. The age 1+ index often indicates a higher, more stable trend than the juvenile index. Sampling is over several year classes which aids in stabilizing the index.

The YOY RSCI (1954-2005) white catfish indices exhibited a significant negative slope over time ($t = -2.58$, $df = 1$, $P < 0.05$, see Table 21). The white catfish age 1+ RSCI index (1954-2005) also exhibited a significant negative slope ($t = -2.52$, $df = 1$, $P < 0.05$). Both white catfish YOY and age 1+ have exhibited extremely low indices from 1998 to the present. White catfish are collected throughout the year and in 2006, most YOY were present from January through March (Figure 23).

YOY channel catfish exhibited no trend over time while the 1+ RSCI (1954-2005) channel catfish indices exhibited a significant increasing slope ($t = 2.14$, $df = 1$, $P < 0.05$, (Tables 23-24). Channel catfish YOY indices were extremely low from 1997 – 2002, increased in 2003 and then decreased through 2004 and 2005 (Figure 25, top). The channel catfish age 1+ RSCI 20051 index was slightly lower than 2004 (Figure 27, bottom).

The channel catfish was introduced to Virginia in the late 1800's (Jenkins and Burkhead, 1994), and their population trends may be a result of the species becoming established and

forming natural cycles as they become integrated into the ecosystem. The YOY declined dramatically since the late 1980's (with the exception of the 1989 year class), and decreased in 20054 (Table 23 and Figure 25, top), possibly due to competition with another introduced catfish, the blue catfish (*I. furcatus*). Older age classes are now beginning to reflect the decline in juveniles (Tables 23- 24 and Figures 25 and 27, top). Most channel catfish YOY were collected in January through March 2006 (Figure 26).

Blue Catfish (*I. furcatus*)- The blue catfish is one of Virginia's largest freshwater or anadromous fishes (Jenkins and Burkhead, 1993). It was introduced to the Chesapeake Bay as a sportfish in the James, Rappahannock and Mattaponi Rivers from 1974 through 1989 (Virginia Department of Game and Inland Fisheries, 1989 as reported by Connelly, 2001) and inhabits main channels and backwaters of medium to large size rivers (Murdy et al., 1997). The blue catfish is a carnivorous bottom feeder that preys on fishes, insects, crayfish, clams, and mussels (Murdy et al., 1997). The blue catfish YOY RSCI (1983-2005) indices exhibited a significant positive slope ($t = 3.68$, $df = 1$, $P < 0.05$) over time (Table 25 and Figure 28). Similarly the 1+ RSCI (1983-2005) blue catfish index exhibited a significant positive slope ($t = 4.23$, $df = 1$, $P < 0.05$). The 2005 YOY RSI index was second only to the 1997 index (Figure 28). The 2005 age 1+ blue catfish RSI index was the highest since the start of the survey index in 1983 (Figure 30, top and Table 26). The two blue catfish age classes are noticeable with those less than 165-175 mm FL belonging to the age 0 year class (Figure 29). Most YOY were collected in March and April 2006, though both age classes were collected throughout the year (Figure 29).

Blue catfish indices have increased dramatically since 2001 and the ecosystem effects of such an increase are unknown. However, with the increase in the age 1+ blue catfish index, both the age 1+ white and channel catfish indices decreased. From March 2004 to April 2005,

invertebrates (mostly amphipods, isopods and mud crabs) dominated the diets of small blue catfish, while larger blue catfish were piscivorous eating mostly menhaden and gizzard shad (*Dorosoma cepedianum*) (Parthree et al., 2006). There is a possibility that the other catfishes (white and channel) are competing with the introduced blue catfish for the same resources.

Northern Puffer (*S. maculatus*) - The puffer is captured in small numbers almost exclusively in the mainstem Bay (Figure 31, bottom). Spawning occurs from May to August in nearshore waters (Murdy et al., 1997), with peak spawning in June and July (Laroche and Davis, 1973). June is the start of the biological year with puffer less than 50 mm TL collected. Puffer is first caught in the Bay in May and usually peaks during late summer/early fall (July to October; see Figure 32).

The puffer RSCI (1955-2005) index did not exhibit any annual trends (Figure 31, top and Table 27). Since 1988, northern puffer indices have shown an overall continuous decline (Figure 31, top).

Silver Perch (*B. chrysoura*) - Silver perch is found in all strata, but the York River often dominates catches (Figure 33, bottom). Spawning occurs in the deep waters of the Bay and offshore from May to July, and juveniles (100 mm TL) enter the Bay by July (Chao and Musick, 1977; Rhodes, 1971). When the RSCI (1955-2005) index was analyzed for annual trends, a significant negative slope was present ($t = -3.70$, $df = 1$, $P < 0.05$; Figure 33, top and Table 28). Highest abundances of YOY silver perch were collected from September through November 2005 (Figure 34).

Blue Crab (*C. sapidus*) - After mating in the oligohaline and mesohaline portions of estuaries, adult female blue crabs migrate to the mouths of estuaries or nearshore coastal waters to overwinter and then spawn the following spring (Van Engel, 1958; Tagatz, 1968). Spawning

occurs from May to September, with a minor peak in June and a major peak in July-August in temperate regions (Dittel and Epifanio, 1982; McConaughay et al., 1983).

Newly-hatched zoea larvae are advected out of the estuary in the net surface outflow (Dittel and Epifanio, 1982; Epifanio et al., 1984), and larval development proceeds in coastal waters to the postlarval stage, the megalopa (Costlow and Bookhout, 1959). Megalopae reinvade the estuary from coastal waters. The dynamics of reinvasion are not yet fully understood, but tidally-timed vertical migration appears important once megalopae reach the mouths of estuaries (Epifanio et al., 1984; Epifanio, 1988). Influx of megalopae appears associated with the neap-spring tidal cycle (van Montfrans et al., 1990) and with downwelling wind events (Goodrich et al., 1989; Little and Epifanio, 1991). Megalopae then settle into shallow water habitats and metamorphose to the first juvenile instar (Orth and van Montfrans, 1987; Mense and Wenner, 1989). Growth is rapid from spring through fall (Lippson, 1971), but blue crabs are inactive during winter. Cold winters adversely affect blue crabs in Chesapeake Bay, with highest mortality occurring in larger crabs (Sharov et al., 2003). Maturity is usually attained after one year of residence in the estuary.

Since 1968, the age 1+ blue crab (crabs greater than 60 mm carapace width or cw) and adult female indices have exhibited significant negative slopes when regressed against year ($t = -2.23$ and $t = -2.85$, respectively; $df = 1$ and $P < 0.05$ for both, see Figure 35, top and Table 29). The age 0 (crabs less than 60 mm cw) and age 1+ crabs appear to exhibit a near decadal periodicity, with the age 1+ crab index exhibiting a significant positive slope when regressed against the age 0 crab index ($t = 3.77$, $df = 1$, $P < 0.05$). This periodicity may be related to decadal oscillations in temperature, river discharge and surface winds which occur in Chesapeake Bay and may affect blue crab recruitment (Austin, 2002). The age 0 index increased

in 2005 compared to 2004 (Figure 35, top and Table 29). The adult female index has remained low since 1992, while the age 0 index has been variable and the age 1+ index has steadily decreased since 1997 (Figure 35, top).

Highest concentrations of age 0 and age 1+ blue crabs were found in the tributaries (Figure 36 and Figure 37, top). Crabs greater than 120 mm cw are either larger males or adult females as few females greater than 120 mm cw are still juveniles. Adult females are usually concentrated in the Bay mainstem (especially during fall and winter; Figure 37, bottom), but can be found in the mid to upper reaches of tributaries during periods of little freshwater inflow (i.e., droughts). Age 2+ males (> 120 mm cw) usually reside exclusively in the tributaries. Large pulses of YOY crabs were present in October and November 2005 (Figure 38). These crabs were likely the result of the typical large spawning event which routinely occurs in June, followed by a smaller spawning event later in the summer. Adult female catch was highest from July through November (Figure 39), as they travel to the lower Chesapeake Bay and Bay mouth to spawn.

American Eel (*A. rostrata*) - The American eel is a catadromous species, present along the Atlantic and Gulf coasts of North America and inland in the St. Lawrence Seaway and Great Lakes (Murdy et al., 1997). The species is panmictic and supported throughout its range by a single spawning population (Haro et al., 2000; Meister and Flagg, 1997). Spawning takes place during winter to early spring in the Sargasso Sea. The eggs hatch into leaf-shaped ribbon-like larvae called leptocephali, which are transported by the ocean currents (over 9-12 months) in a generally northwesterly direction. Within a year, metamorphosis into the next life stage (glass eel) occurs in the Western Atlantic near the east coast of North America. Coastal currents and active migration transport the glass eels into rivers and estuaries from February to June in

Virginia and Maryland. As growth continues, the eel becomes pigmented (elver stage) and within 12 –14 months acquires a dark color with underlying yellow (yellow eel stage; Facey and Van Den Avyle, 1987). Many eels migrate upriver into freshwater rivers, streams, lakes, and ponds, while others remain in estuaries. Most of the eel’s life is spent in these habitats as a yellow eel. Age at maturity varies greatly with location and latitude, and in Chesapeake Bay may range from 8 to 24 years, with most being less than ten years old (Owens and Geer, 2003). *A. rostrata* from Chesapeake Bay mature and migrate at an earlier age than eels from northern areas (Hedgepeth, 1983). Upon maturity, eels migrate back to the Sargasso Sea to spawn and die (Haro et al., 2000). Metamorphosis into the silver eel stage occurs during the seaward migration that occurs from late summer through autumn.

The current American eel index is composed of all size eels collected in the upper half of each of the major tributaries (JA 3 and 4, YK 3 and 4, and RA 3 and 4) during the months of April through June. The overall eel RSI CPUE (1955-2006, see Table 30) did not exhibit a trend, but the index values since 1983 have shown a significant negative slope over time ($t = -6.55$, $df = 1$, $P < 0.05$; Figure 40, top). American eel are collected by the trawl exclusively in the tributaries (Figure 40, bottom). During the June 2005 to May 2006 project period, eels were collected each month (Figure 41).

Bay Anchovy (*A. mitchilli*)- The bay anchovy is the most abundant finfish throughout Chesapeake Bay and its tributaries found in salinities ranging from 1-33 psu (Murdy et al., 1997). Bay anchovy feed mostly on zooplankton and are an important food source for many other Bay fishes (Murdy et al., 1997). In years of “normal” freshwater inflow (i.e., 1997-2000), Atlantic menhaden, bay anchovy and Atlantic croaker often dominate fish biomass in Chesapeake Bay (Jung, 2002). The overall bay anchovy RSI index (1955-2005) did not exhibit a

trend (Table 31; Figure 42, top). The 2005 bay anchovy RSI index was slightly greater than the 2004 index. Bay anchovy are ubiquitous in the trawl survey catches (Figure 42, bottom) and are collected throughout the year (Figure 43).

Atlantic Menhaden (*B. tyrannus*)- Menhaden spawn in the spring (March through May) and fall (September through October) in shelf waters off Chesapeake Bay (Murdy et al., 1997). Larval migration into estuaries occurs October through June in the mid-Atlantic (Rogers and Van Den Avyle, 1989). Larvae (10-34 mm TL) appear in the Bay in large numbers in May and June, with a smaller pulse in November (Murdy et al., 1997). Larvae utilize brackish and freshwater as nursery areas to metamorphose into juveniles and often reach 40-185 mm standard length (SL) by Fall. YOY leave the bay in late Fall and migrate southward in dense schools (Murdy et al., 1997). Low dissolved oxygen events in the summer can lead to large mortalities in the Bay (Murdy et al., 1997). Menhaden are filter feeders and are key prey for various piscivorous species in Chesapeake Bay such as striped bass, weakfish and blue catfish (Parthreee et al., 2006). The 2006 Atlantic menhaden index decreased compared to 2005 (Figure 44, top) and menhaden were distributed both in the tributaries and the Bay mainstem (Figure 44, bottom). During the survey period, most YOY menhaden were collected in June 2005 and February and March 2006.

DISCUSSION

Chesapeake Bay constitutes a major nursery area for most of the species examined and is one of several along the Atlantic seaboard. With the exception of weakfish and the anadromous species, all of the juveniles recruited to the Chesapeake Bay nursery areas result from spawning activities which take place outside of the Bay. Early juveniles of the four sciaenid species are thought to be estuarine dependent, but black sea bass young-of-year also utilize nearshore

continental shelf waters (Musick and Mercer, 1977) and juvenile summer flounder also frequent shallow, high salinity coastal lagoons (Wyanski, 1989). Scup do not appear in the Bay in appreciable numbers until they are nearing one year old. Conceivably, Chesapeake Bay nursery zone abundances may well be reflective of overall reproductive success.

Four estimates of relative abundance were historically developed for juvenile finfish and blue crabs in this survey. The values reported as the Bay and River index (BRI) were only for the historic fixed stations transects of the tributaries and the Bay survey established in 1988. Two indices were presented, one from the tributaries only (RO; 1979 to present) and the other for both the Bay and rivers (BRI; 1988 to present). Analyses were conducted on the long time-series (RSCI and RSI) for the target species discussed.

Efforts continue on validating older data, and comparing these historical values against data presently being collected, and creating new indices for species of emerging ecological importance such as Atlantic menhaden. Additionally, the now fully implemented random stratified survey of the tributaries has enhanced the ability to produce reliable estimates of juvenile abundance. These surveys have complimented and correlated with the fixed mid-channel transects quite well since their inception in June 1991 (Geer and Austin, 1996a; Geer and Austin, 1999).

Juvenile indices collected by the VIMS trawl survey are instrumental in helping to forecast year class strength, avoid stock collapse and verify management strategies. It is imperative that any early warning signs of stock decline are recognized before commercial landings reflect the declines. For instance, the current Interstate Fisheries Management Plan for striped bass relies heavily on juvenile abundance estimates to determine action levels for the intensification or relaxation of harvest restrictions. Low year classes during much of the 1970's

and mid-1980's led to a striped bass moratorium in 1985, which lasted until 1990 (Seltzer-Hamilton, 1991b). Evidence of a very poor year class of summer flounder was first detected by the VIMS Trawl Survey, was recognized by the Mid-Atlantic Fisheries Management Council (MAFMC) as the only available index of summer flounder recruitment and was instrumental in shaping more protective harvest regulations in Virginia. The VIMS Trawl Survey spot index is the only spot index available on the East Coast and was essential for the 2004 ASMFC Spot FMP Review (ASMFC, 2004). Though the trawl is not the preferred gear to catch American eel, VIMS Trawl eel indices played an important role in both the upcoming 2006 ASMFC American Eel FMP (ASMFC, 2006) and the U.S. Fish and Wildlife Services American Eel Status Review. Assessment of annual recruitment success for coastal Atlantic finfish populations should involve multi-state monitoring efforts, and would validate area-specific juvenile indices.

The trawl survey is also important for monitoring interfamily interactions. For example, annual catch rates of channel catfish and white catfish have declined since 1991, while those of blue catfish, which was introduced in Virginia during the 1970's and 1980's, to enhance sportfishing, have increased dramatically (Connelly, 2001; this report). Additionally current bistrate FMP's utilize trawl survey blue crab data as the foundation for understanding blue crab population dynamics in the Chesapeake Bay, and were used to construct the Virginia blue crab sanctuary corridor.

Declines in catches of the aforementioned important recreational species are most often due to degradation of their estuarine nursery habitats, overfishing and year class failure (Murdy et al., 1997). Spot indices have declined greatly over the past 50 years, with the RSCI 1955-1978 index twice that of the 1979-2005 index. Spot are oceanic spawners and their year class strength appears to be controlled by environmental factors occurring outside the Bay (Homer and

Mihursky, 1991; Bodolus, 1994). Croaker show the greatest interannual variability of the key species discussed, with fluctuations most probably weather related, with particular correlations to hurricane activity (Montane and Austin, 2005). The timing of croaker recruitment to the Bay (August-December) corresponds with normal peak hurricane activity to the region. Norcross (1983) and Murdy et al., (1997) suggest cold winters cause increased mortality in overwintering YOY croaker and during some years may cause the spawning population to be pushed further south, preventing the postlarval fish access to Bay nursery areas. Larger blue crabs may also exhibit increased mortality during colder winters in Chesapeake Bay (Sharov et al., 2003). Weakfish are a prized recreational species, but their indices have remained low since the mid-1990's, and their decline may be attributed to both habitat degradation and overfishing (Murdy et al., 1997). Declines in summer flounder have been due to overfishing and year class failure (Murdy et al., 1997), and these were apparent in the very low 1987 trawl index. The 2004 black sea bass index has been highly variable over the duration of the survey and was the lowest since 1968. The scup index has been highly variable over the duration of the survey, but low since 1993.

Striped bass and white perch indices were very low during the 1970's and early 1980's. Striped bass display great recruitment variability and one or two strong year classes may dominate the population (Murdy et al., 1997). After closure of the fishery in the mid to late 1980's due to overfishing, poor recruitment and low stock abundance (Seltzer-Hamilton, 1991b), the index had increased, peaked in 1987 and significantly decreased thereafter. White and channel catfish indices while variable, have decreased dramatically over the past 13-14 years, most probably due to overfishing, or competition with their congener, blue catfish.

The VIMS Trawl Survey is a key element for future management of fishery resources that utilize the Chesapeake Bay as spawning and nursery grounds. Because the Chesapeake Bay constitutes a major nursery area for many coastal migratory fish species, monitoring annual recruitment is a key element in multi-state management efforts along the Atlantic Coast. These data will continue to provide managers with valuable predictive tools for assessing the success of present management measures.

NUMBER OF TRAWLS:	1,332		1,384		1,118		1,249		1,102		1,224		1,224		1,211	

1. Based on the number of occurrences of a habitat type divided by the total number of trawls.

2. Sand and Mud are used when verification can be confirmed by direct observation.

3. Unknown is used when none of the categories are found in the trawl.

Abundance is estimated relative to the capacity of a commercial test note (internal dimensions 25.7" x 16.6" x 10", approximately 72 liters).

Categories include: 0.5 = < 1/4 bin, 1 = 1/4 bin, 2 = 1/2 bin, 3 = 3/4 bin, 4 = full bin, etc.

KEY

Sample Type:	ALL	All fish species and blue crabs sampled, VIMS code 104
	CRAB	Only blue crabs sampled, VIMS code 102
	FISH	Only fish species sampled, VIMS code 090
System:	CL	Lower Chesapeake Bay (Virginia Portion)
	JA	James River
	PO	Potomac River
	RA	Rappahannock River
	YK	York River
	ZZ	includes: Atlantic Ocean (AT) - 1971, 78-79; Piankatank R. (PK) - 1970-71, 98-00; Mobjack Bay (MB) - 1970-73, 98-01; Pocomoke Sound (CP) -1973-81, 98-01; Great Wicomico R. (GW) - 1998-00.
Vessel:	BR	W.K. Brooks
	FH	Fish Hawk
	JS	Captain John Smith, J1 prior to 1986.
	LA	Langley
	PA	Pathfinder
	RE	Restless
	OT	Includes: Aquarius (AQ) - 1978; Investigator (IN) - 1970; Judith Ann (JA) - 1981; Langley II (LN) - 1985,2001; Sally Jean (SJ) - 1981; Outboard Skiff (SK) - 1970-71; Three Daughters (TD) - 1978; Virginia Lee (VL) - 1955-57; Edith May (EM) - 1984.
Gear Code:	010	Unlined, no tickler chain, 30' bridle, 48"x22" otter board doors, U_N_3B_SW
	033	Lined, no tickler chain, 30' bridle, 48"x22" doors, L_N_3B_SW
	043	Unlined, tickler chain, 30' bridle, 54"x24" doors, U_T_3B_LW
30' Gears	068	Lined, tickler chain, 30' bridle, 54"x24" otter board doors, L_T_3B_LW
	070	Lined, tickler chain, 60' bridle, 54"x24" doors, L_T_6B_LW
	108	Lined, tickler chain, 60' bridle, metal china-v doors, L_T_6B_CV
OT includes 3 configurations of 16 foot nets.		
	035:	Lined, no tickler chain, 23' bridle, 24"x12" otter board doors, 16L_N_2B_SW. Main Gear used
	009:	Unlined, no tickler chain, 16U_N_2B_SW. 19 tows in 1972.
	067:	Lined, w/ tickler chain, 16L_T_2B_SW. 60 samples on the Elizabeth River in 1982-83.
Station Type:	F - Fixed	
	R - Random	
Tow Type:	OT is tow duration in minutes for those not listed. DIS is distance, always 0.25 nautical miles. Equates well to 5 minute duration.	

All Codes found on table from Wojcik and Van Engel, 1988. Appendices A – C

FIGURES

Figure 1. The VIMS Trawl Survey random stratified design of the Chesapeake Bay. Transect lines indicate geographic regions as designated below. (* indicates areas not presently sampled).

Chesapeake Bay	B1	Bottom Bay
	B2	Lower Bay
	B3	Upper Bay
	B4	Top Bay
James River	J1	Bottom James
	J2	Lower James
	J3	Upper James
	J4	Top James
	J5*	Freshwater James 1
	J6*	Freshwater James 2
	JE*	Elizabeth River (sampled for EFH 11/99-5/00)
	JC*	Chickahominy River
York River	Y1	Bottom York
	Y2	Lower York
	Y3	Upper York
	Y4	Top York (lower Pamunkey River)
	PM*	Pamunkey River
	MP1*	Lower Mattaponi
	MP2*	Upper Mattaponi
Rappahannock River	R1	Bottom Rappahannock
	R2	Lower Rappahannock
	R3	Upper Rappahannock
	R4	Top Rappahannock
	R5*	Freshwater Rappahannock
	RC*	Corrotoman River
Potomac River	P1*	Potomac (River Mile 0-10)
	P2*	Potomac (River Mile 10-20)
	P3*	Potomac (River Mile 20-30)
Mobjack Bay	MB*	(re-established July 1998; discontinued 2001)
Atlantic Ocean	AT*	
Piankatank River	PK*	(re-established as of July 1998; discontinued 2001)
Pocomoke Sound	CP*	(re-established as of July 1998; discontinued 2001)
Great Wicomico River	GW*	(as of July 1998; discontinued 2001)

Figure 1 (cont.)

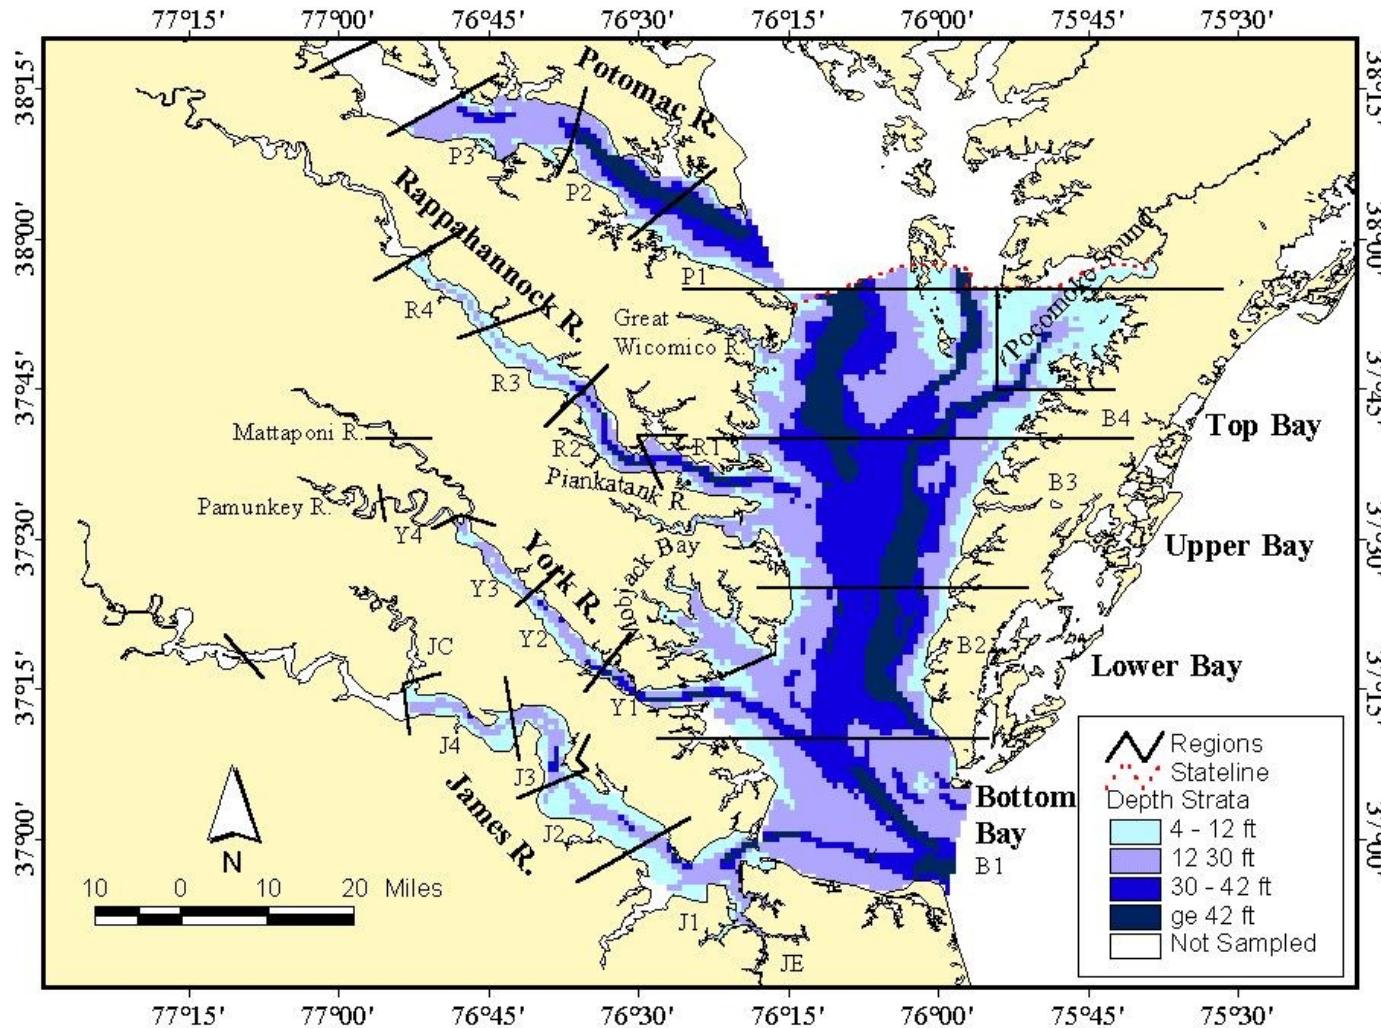

Figure 2. VIMS Juvenile Fish and Blue Crab Trawl Survey Sampling Changes
1955-2005

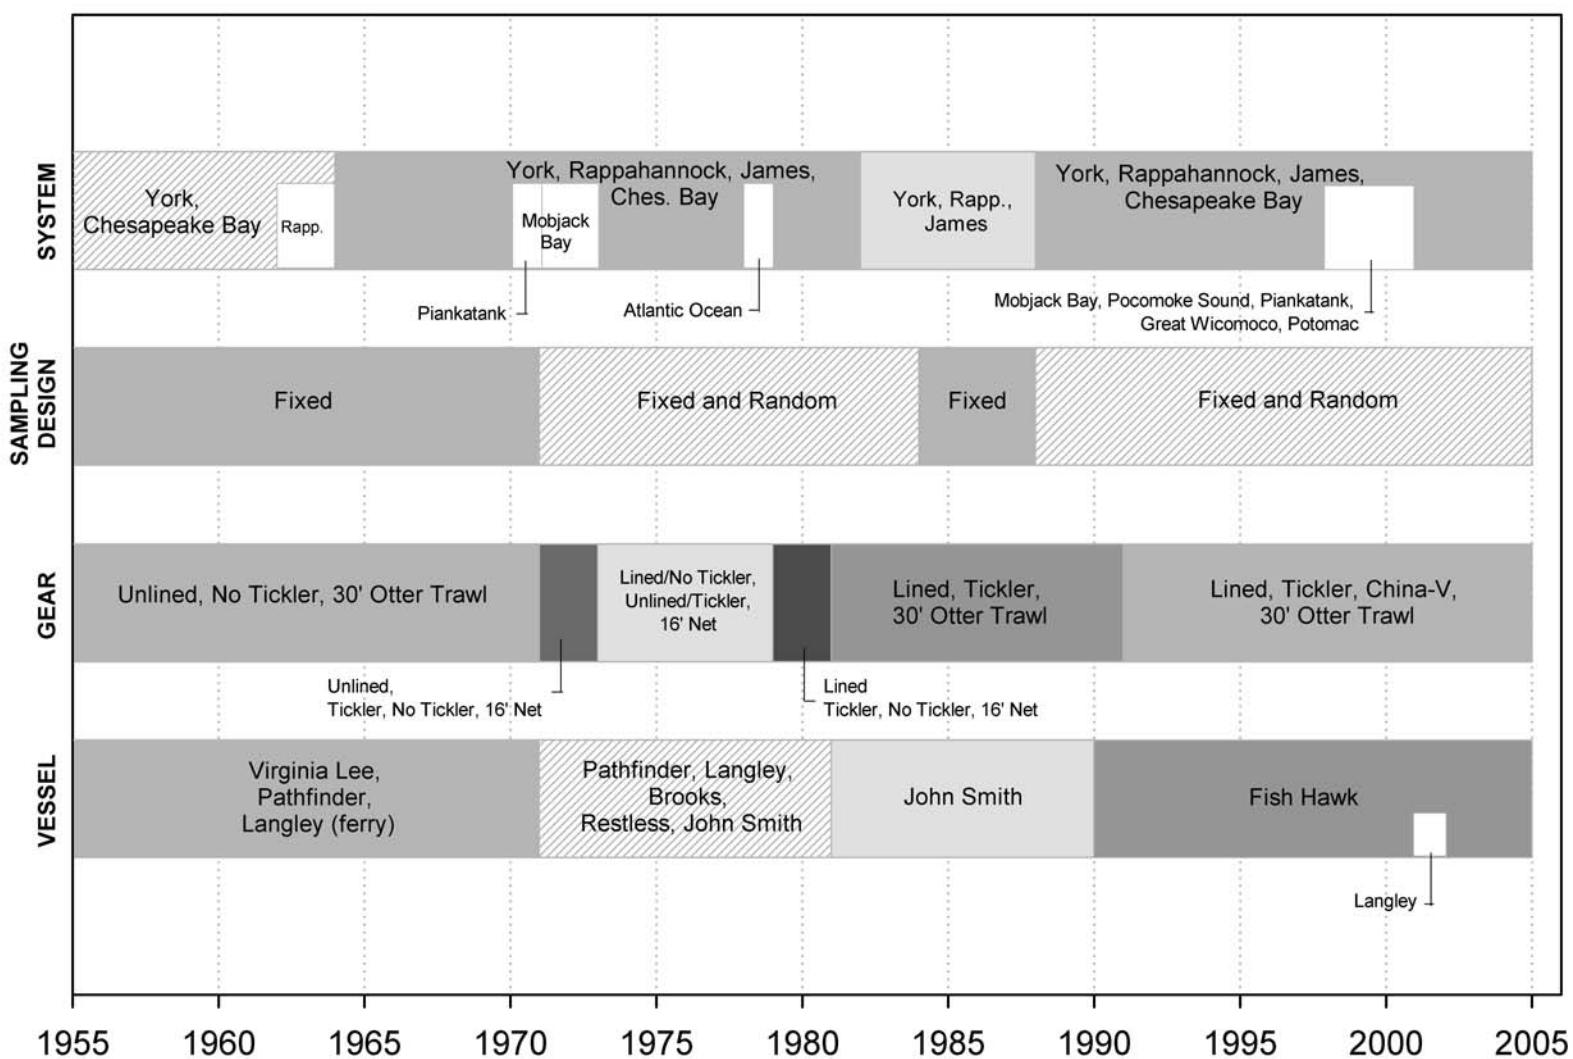

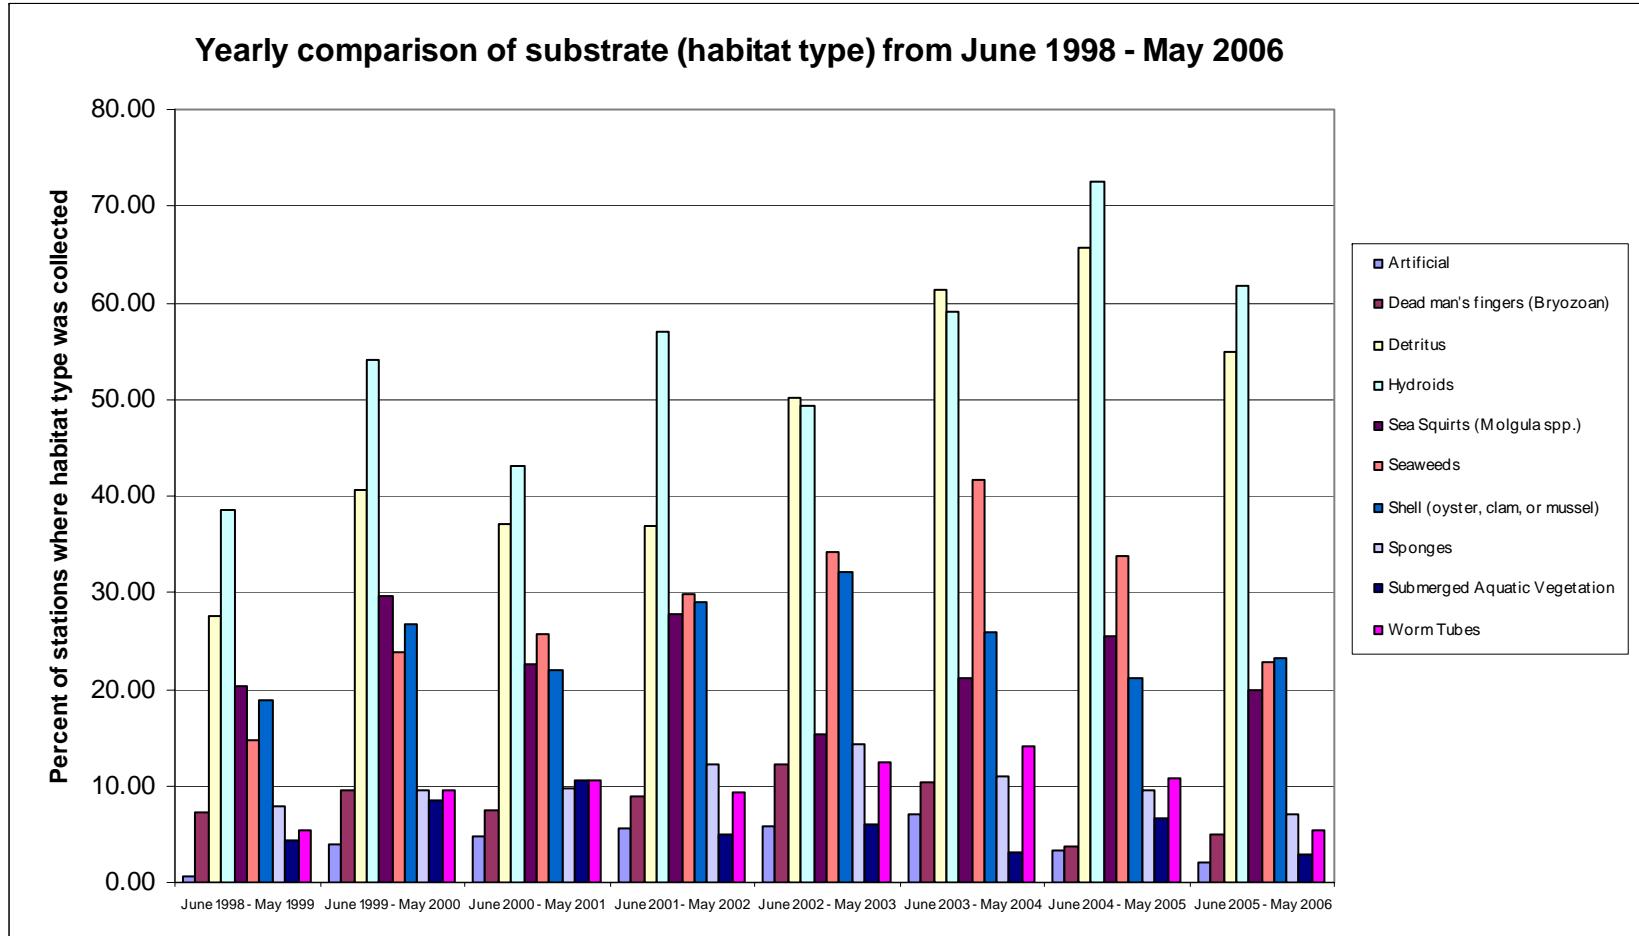

Figure 3.

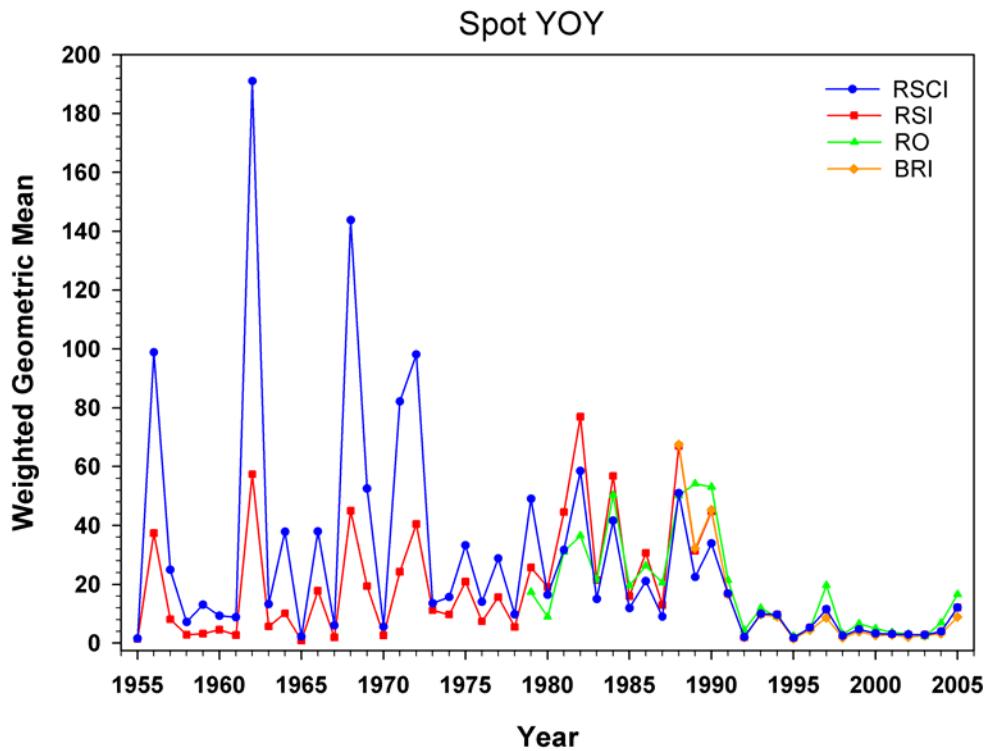

Figure 4. YOY spot random stratified (RSI), random stratified converted (RSCI), fixed transect (Rivers Only-RO), and Bay and fixed river station (BRI) indices (**top**), and distribution of YOY spot from June 2005 through May 2006 (**bottom**).

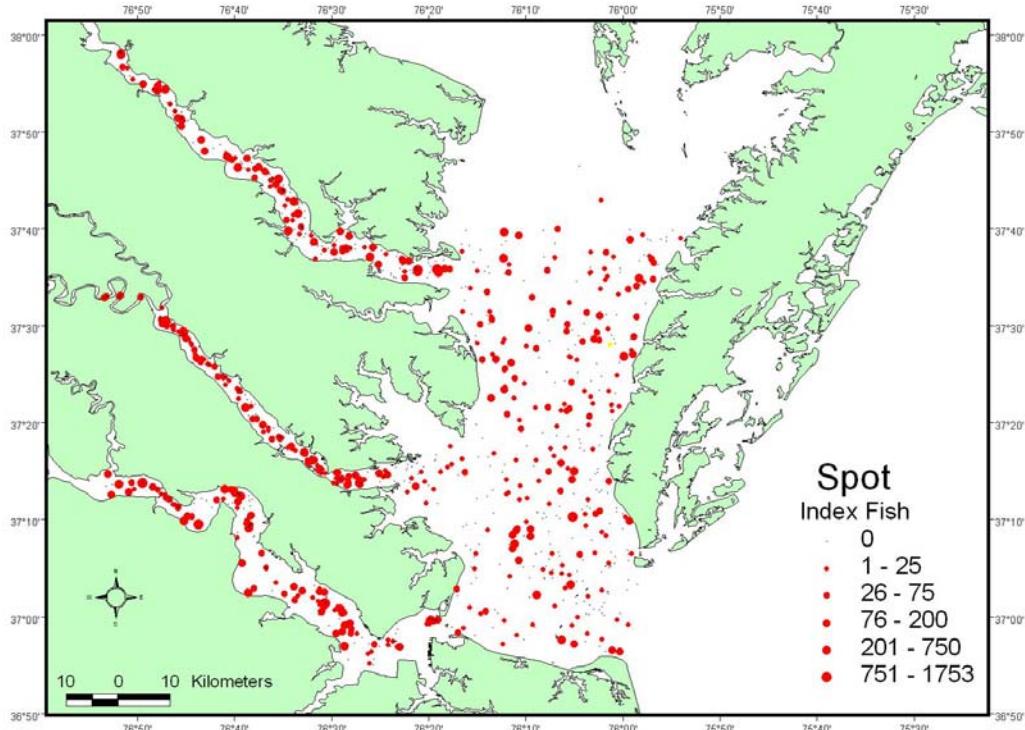

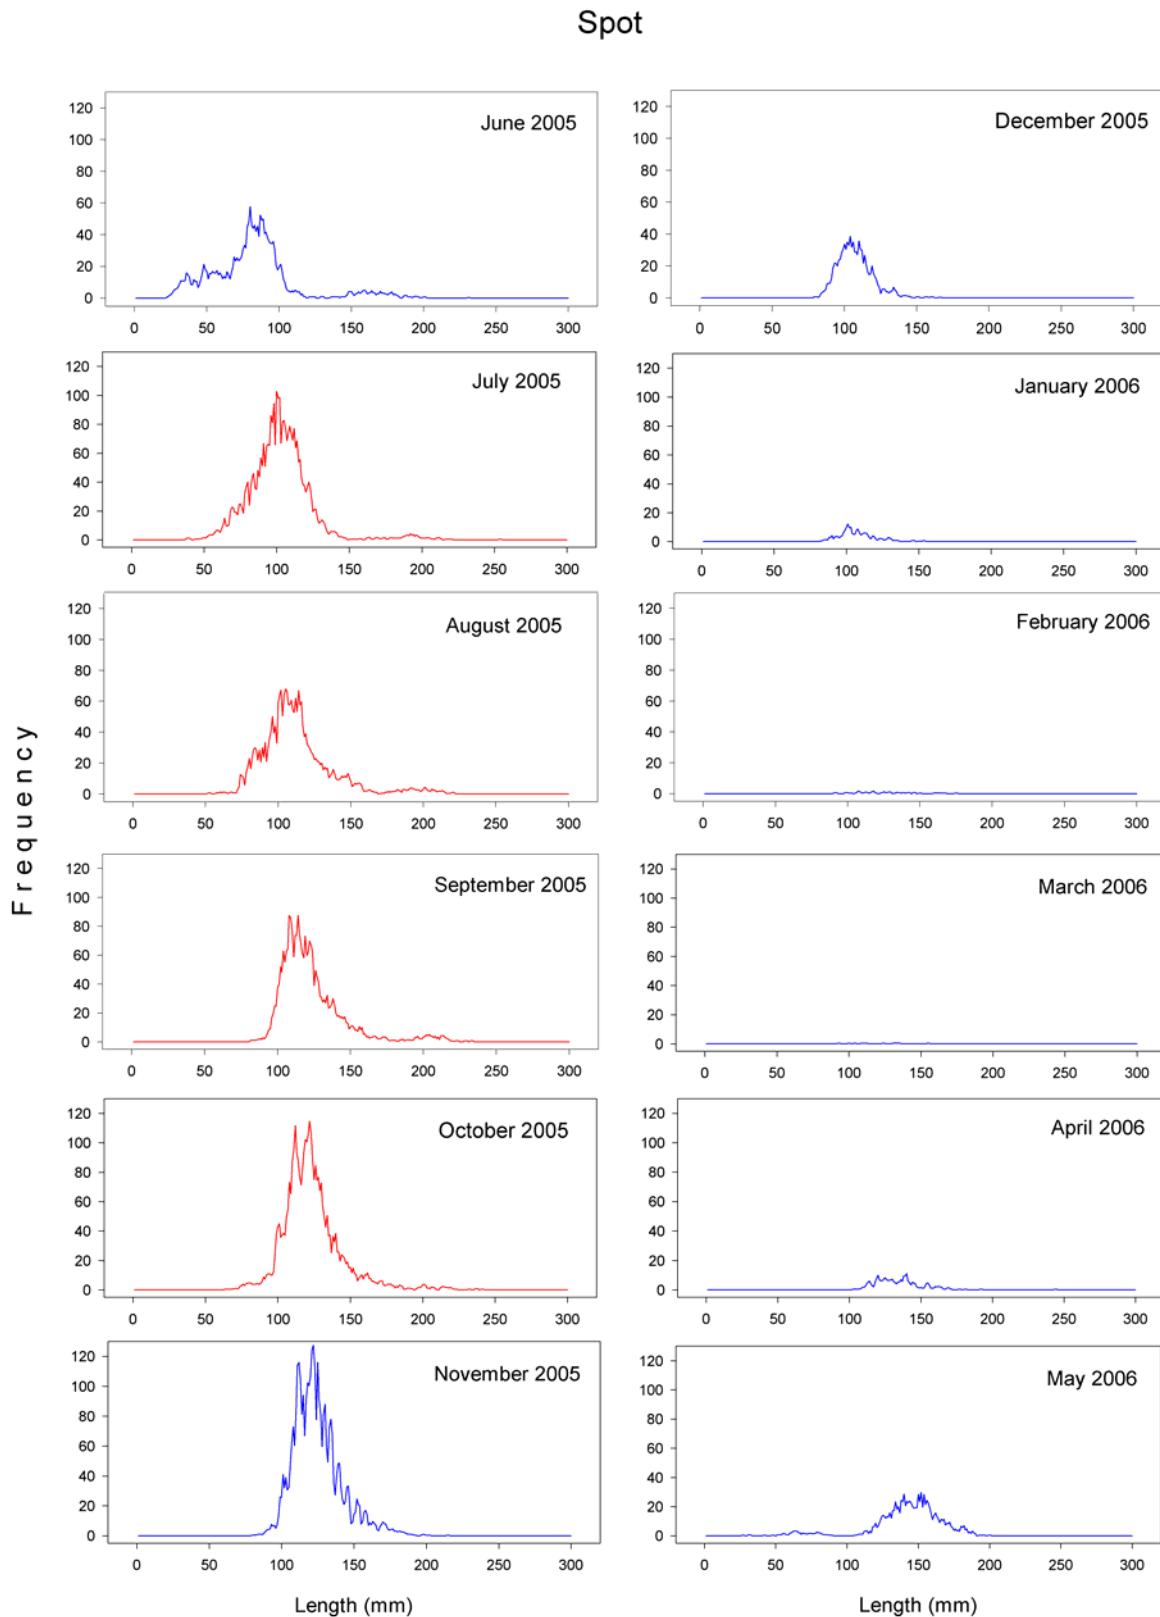

Figure 5. Size frequency of spot by month for June 2005 to May 2006. Index months for spot are shown in red.

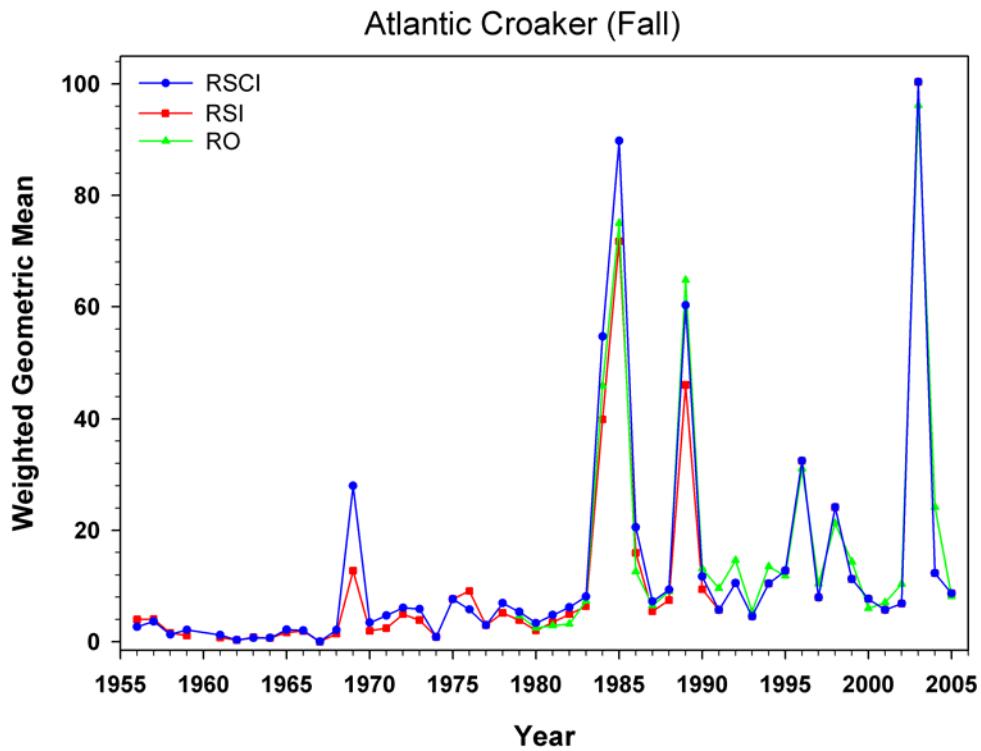

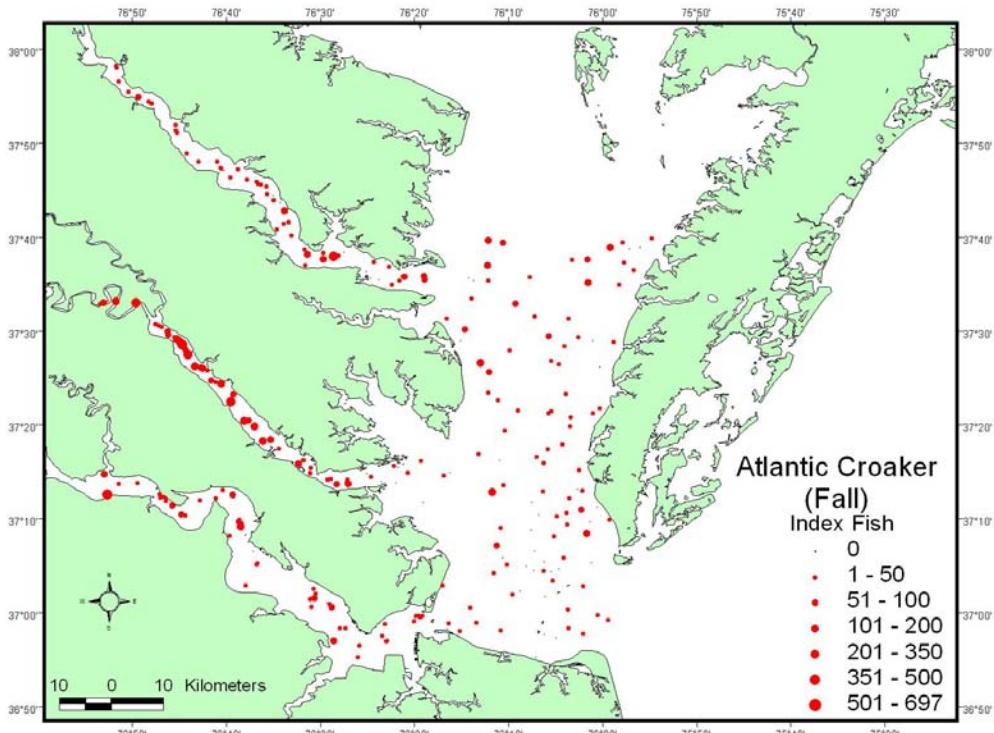

Figure 6. Fall YOY Atlantic croaker random stratified (RSI), random stratified converted (RSCI), fixed transect (Rivers Only-RO), and Bay and fixed river station (BRI) indices (**top**), and distribution of fall YOY Atlantic croaker from October 2005 to December 2005 (**bottom**).

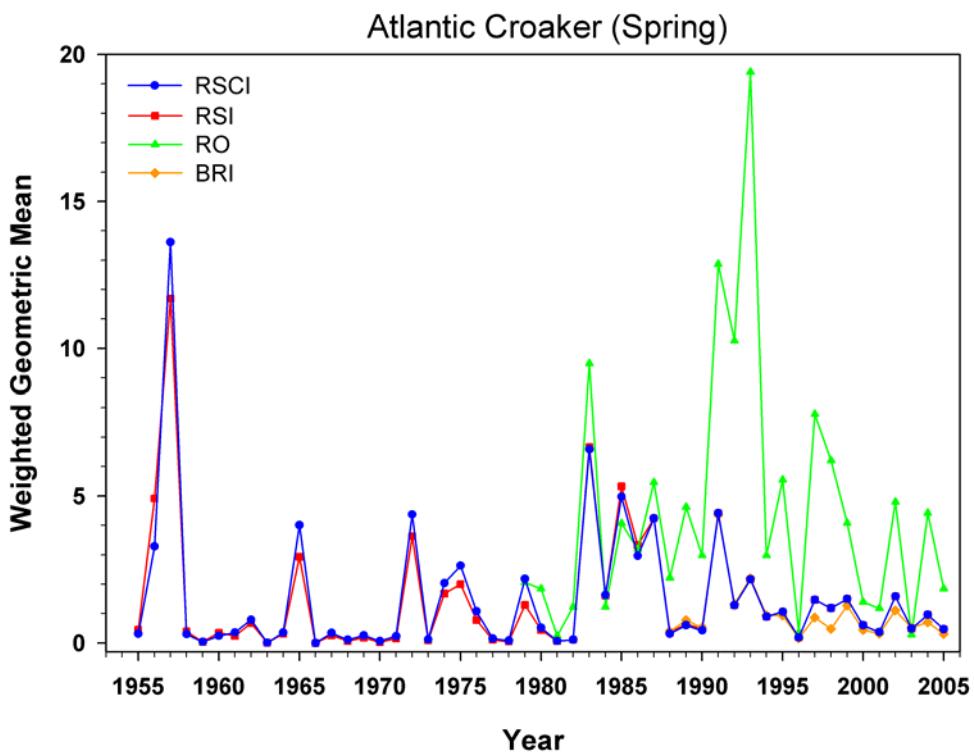

Figure 7. Spring YOY Atlantic croaker random stratified (RSI), random stratified converted (RSCI), fixed transect (Rivers Only-RO), and Bay and fixed river station (BRI) indices (**top**), and distribution of spring YOY Atlantic croaker from June 2005 through August 2005 and May 2006 (**bottom**).

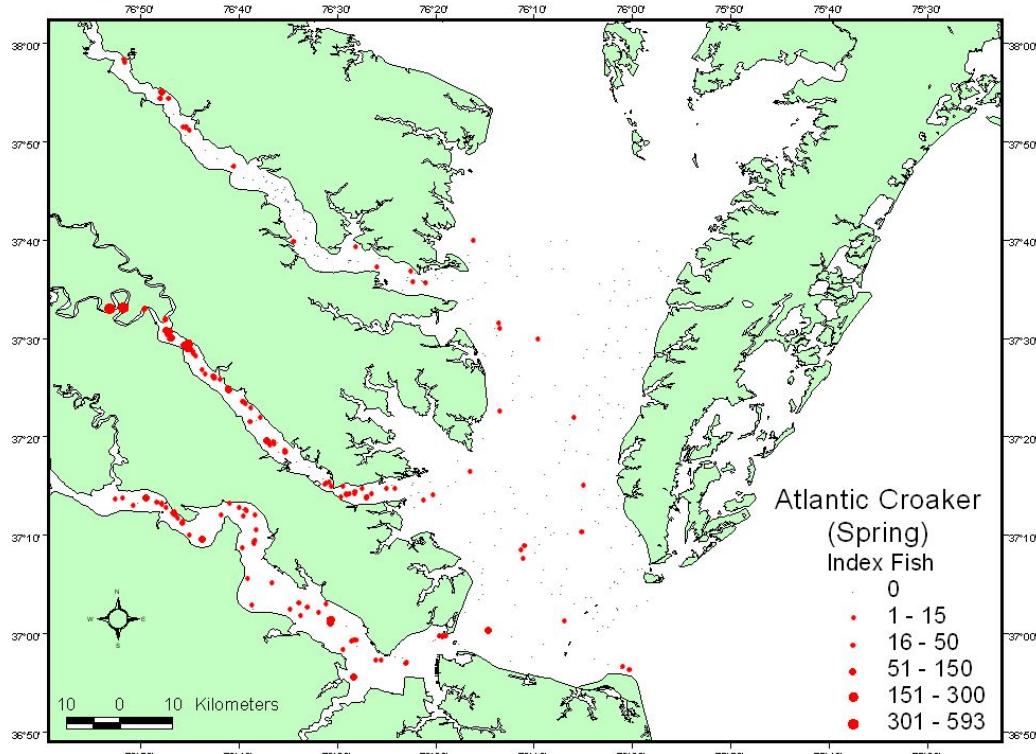

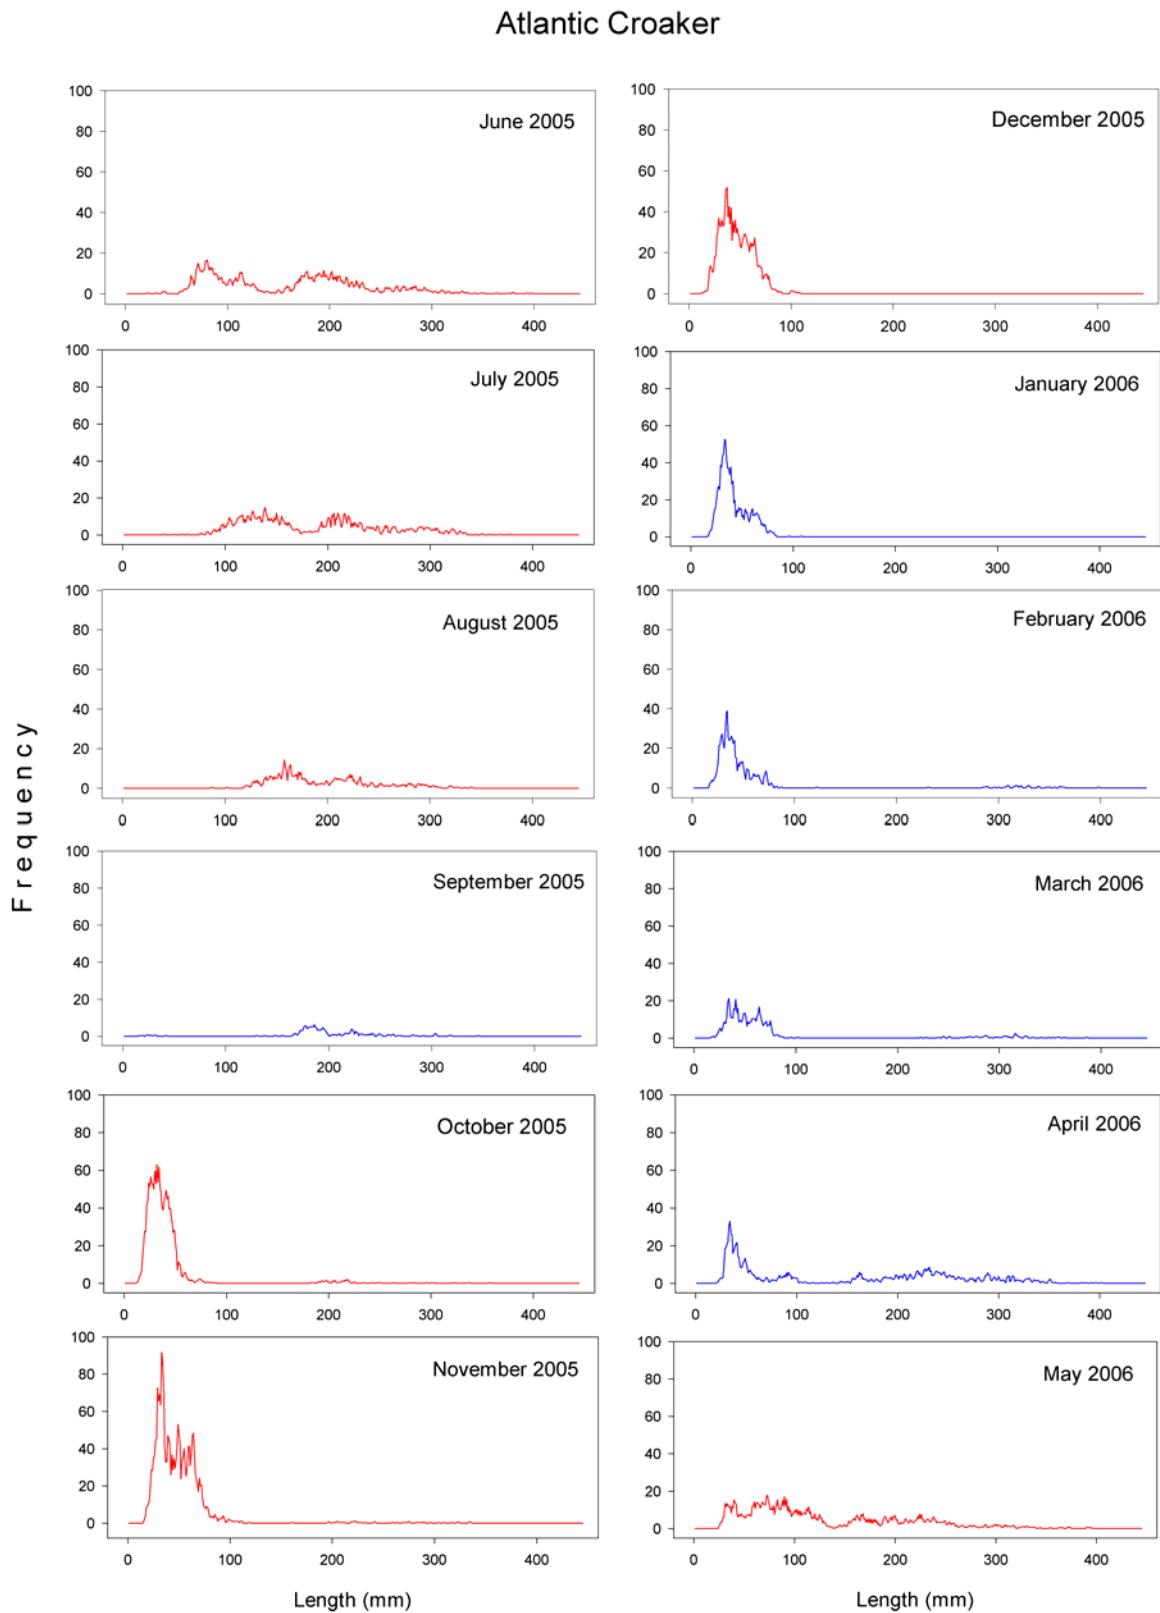

Figure 8. Size frequency of Atlantic croaker by month for June 2005 to May 2006. Index months (fall and spring) are shown in red.

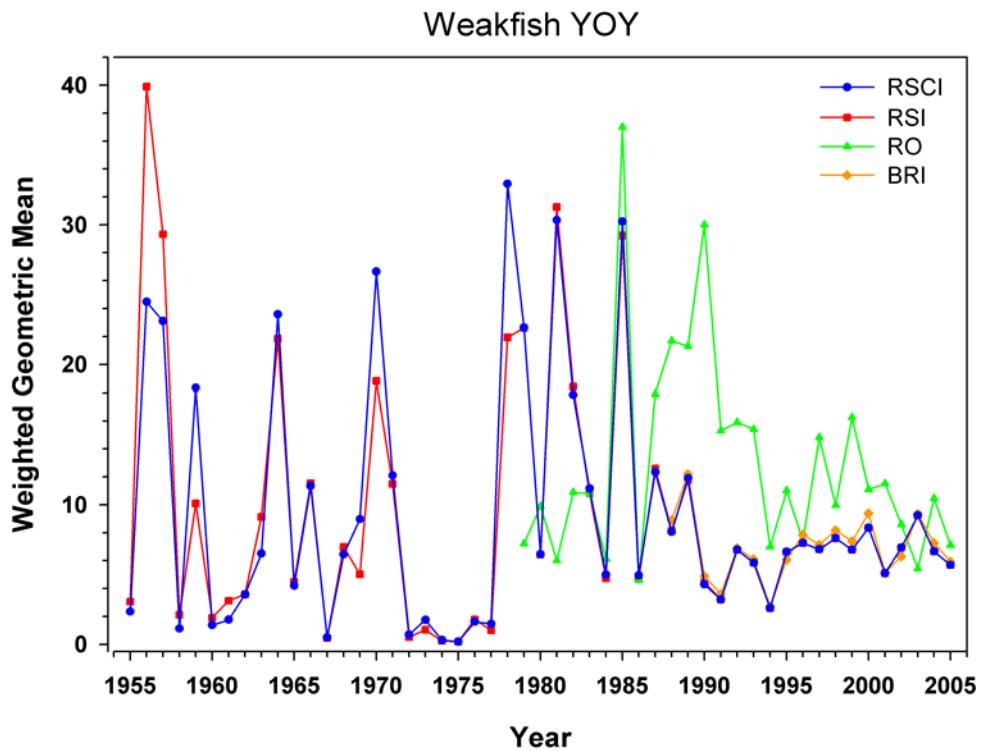

Figure 9. YOY weakfish random stratified (RSI), random stratified converted (RSCI), fixed transect (Rivers Only-RO), and Bay and fixed river station (BRI) indices (**top**), and distribution of YOY weakfish from June 2005 through May 2006 (**bottom**).

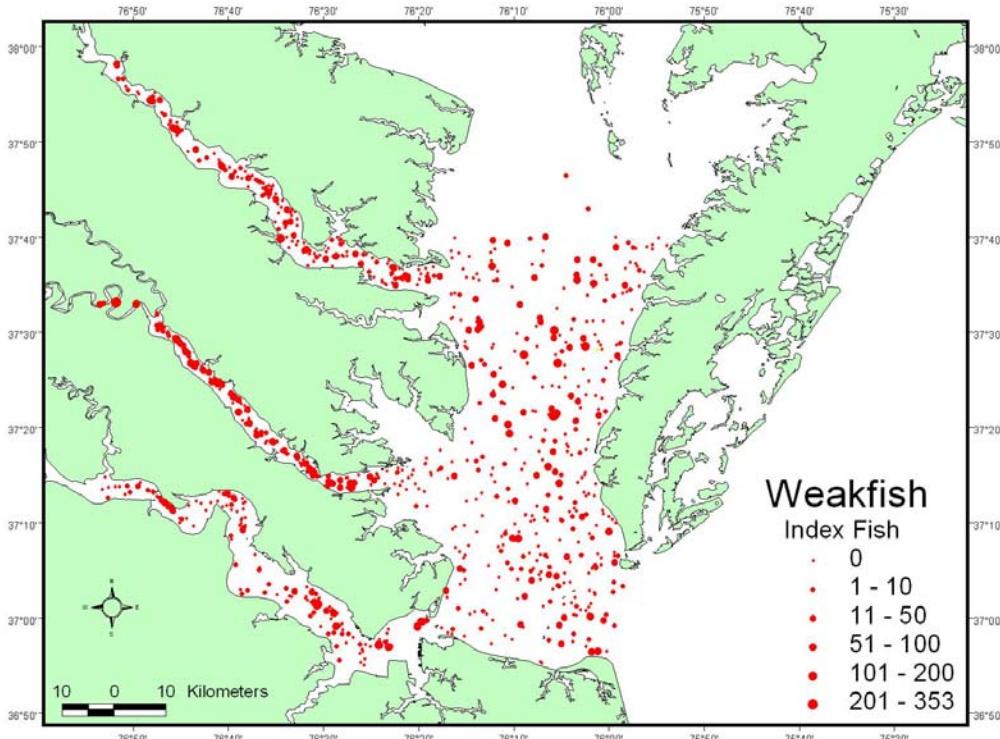

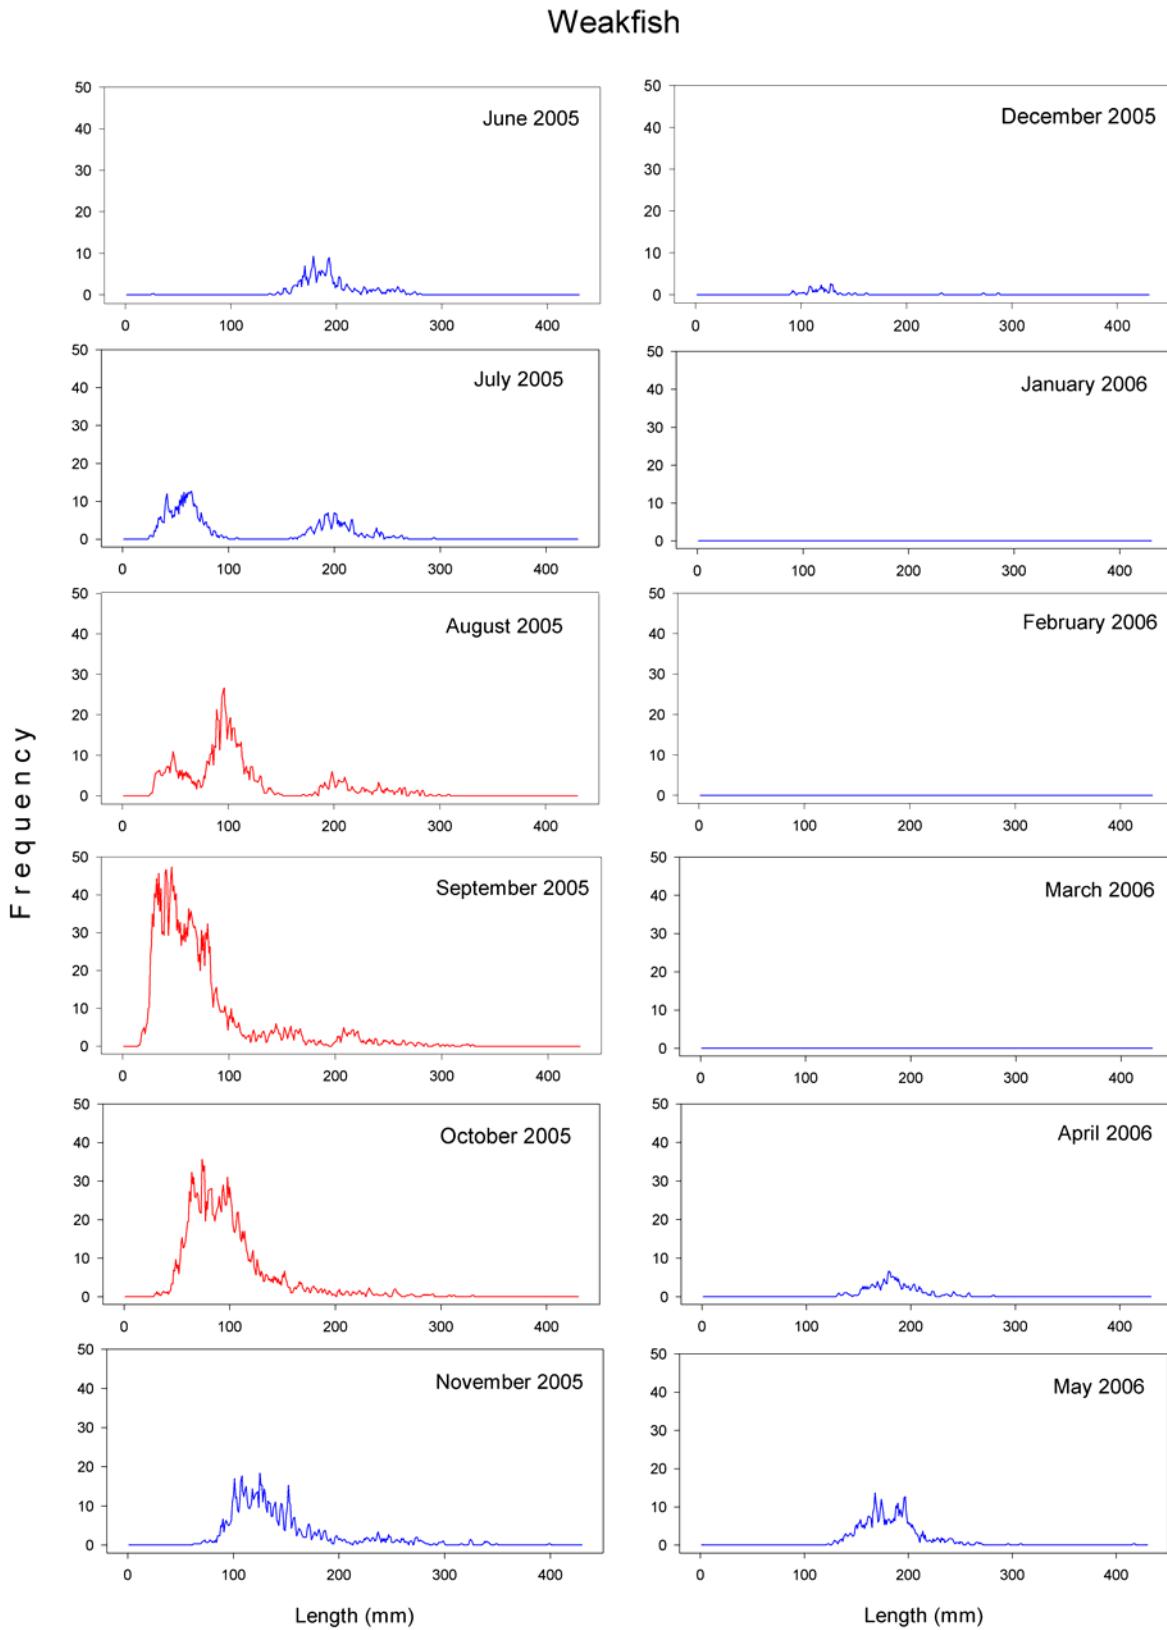

Figure 10. Size frequency of weakfish by month for June 2005 to May 2006. Index months are shown in red.

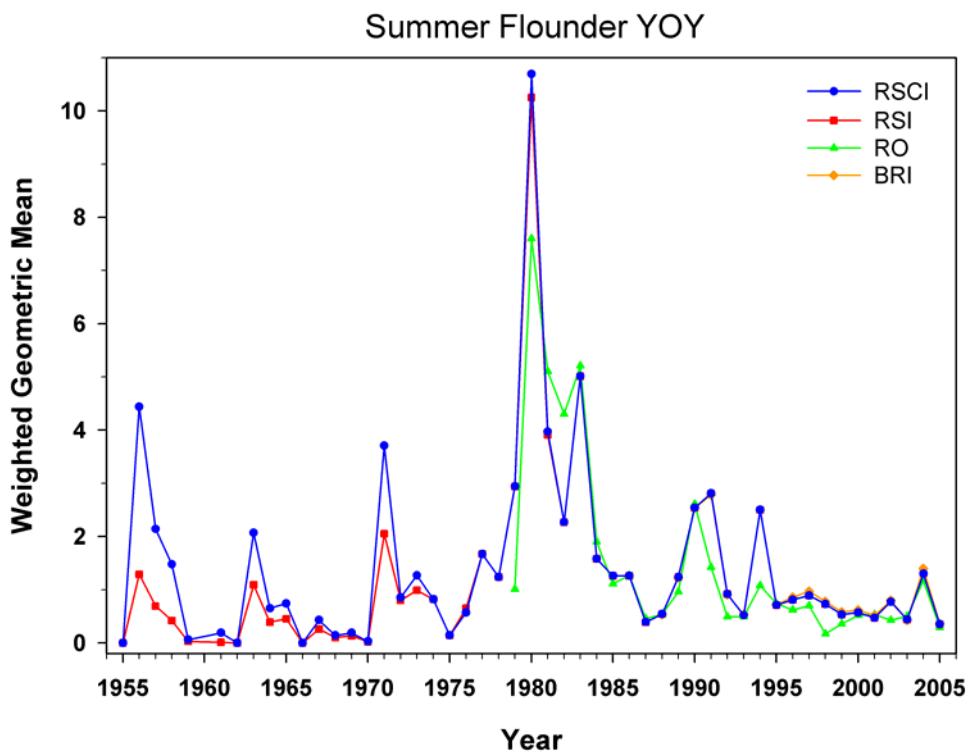

Figure 11. YOY summer flounder random stratified (RSI), random stratified converted (RSCI), fixed transect (Rivers Only-RO), and Bay and fixed river station (BRI) indices (**top**), and distribution of YOY summer flounder from June 2005 through May 2006 (**bottom**).

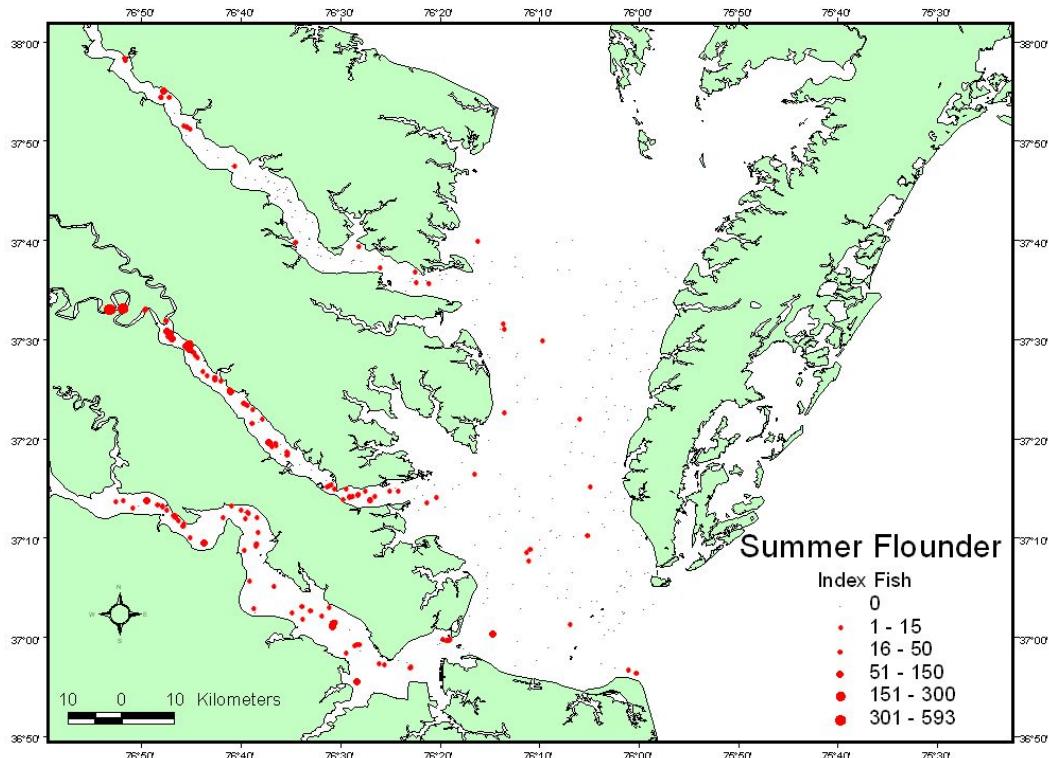

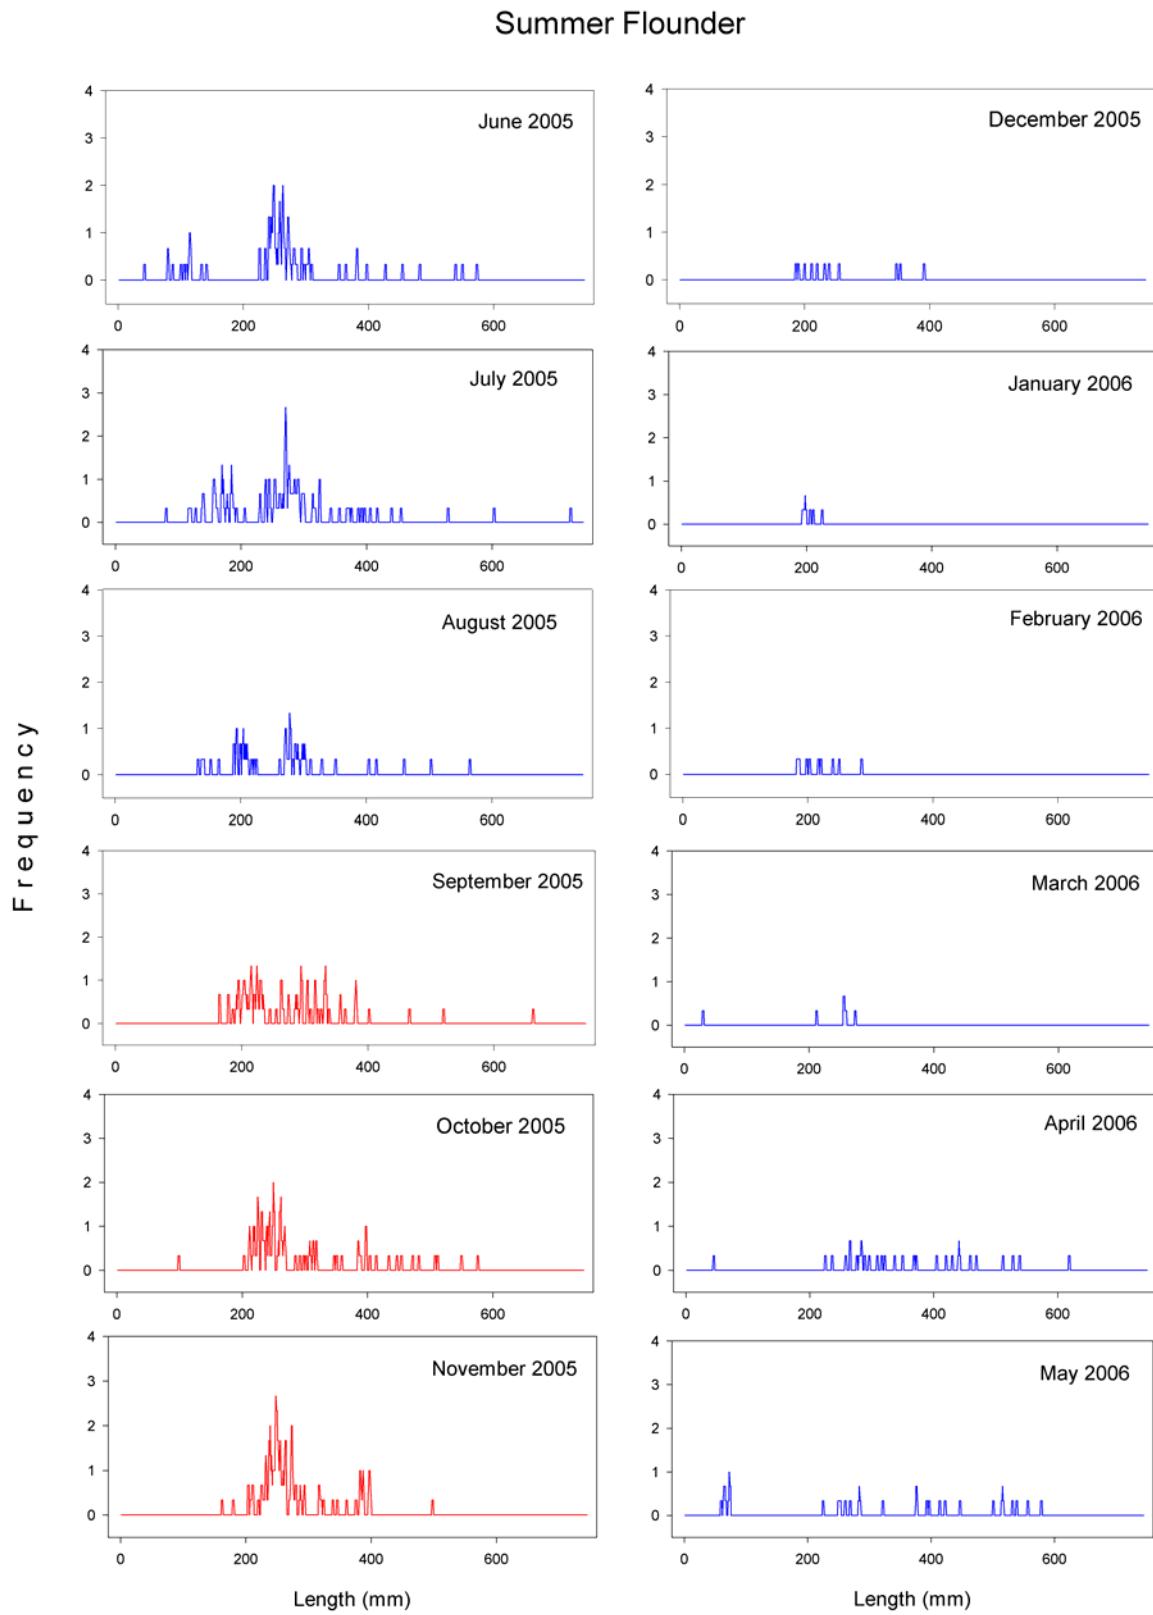

Figure 12. Size frequency of summer flounder by month for June 2005 to May 2006. Index months are shown in red.

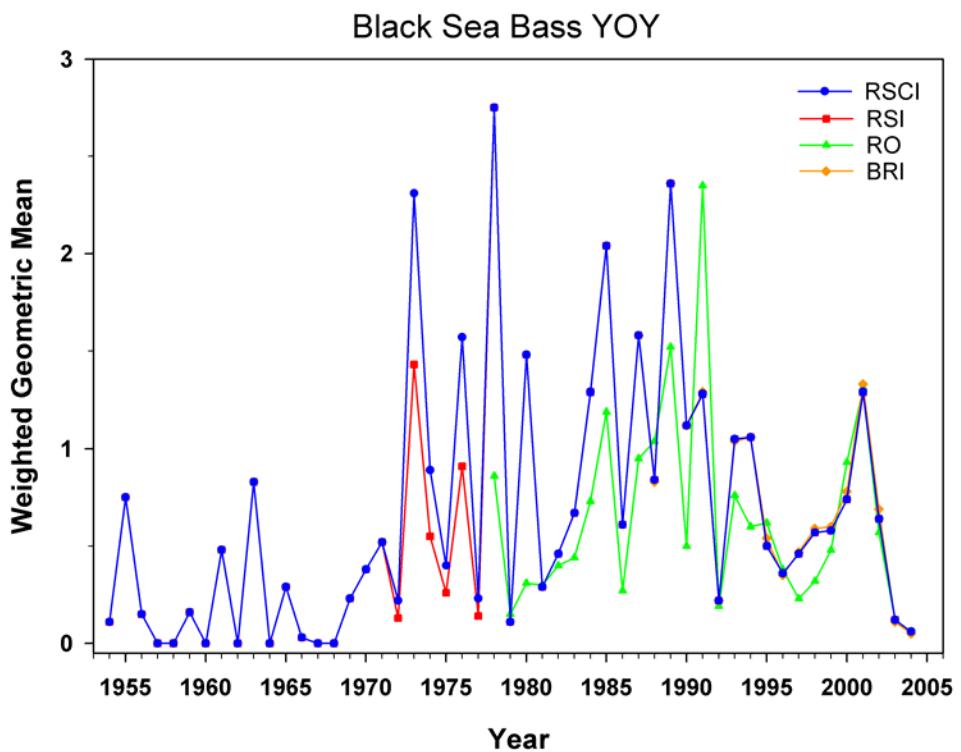

Figure 13. YOY black sea bass random stratified (RSI), random stratified converted (RSCI), fixed transect (Rivers Only-RO), and Bay and fixed river station (BRI) indices (**top**), and distribution of YOY black sea bass from June 2005 through May 2006 (**bottom**).

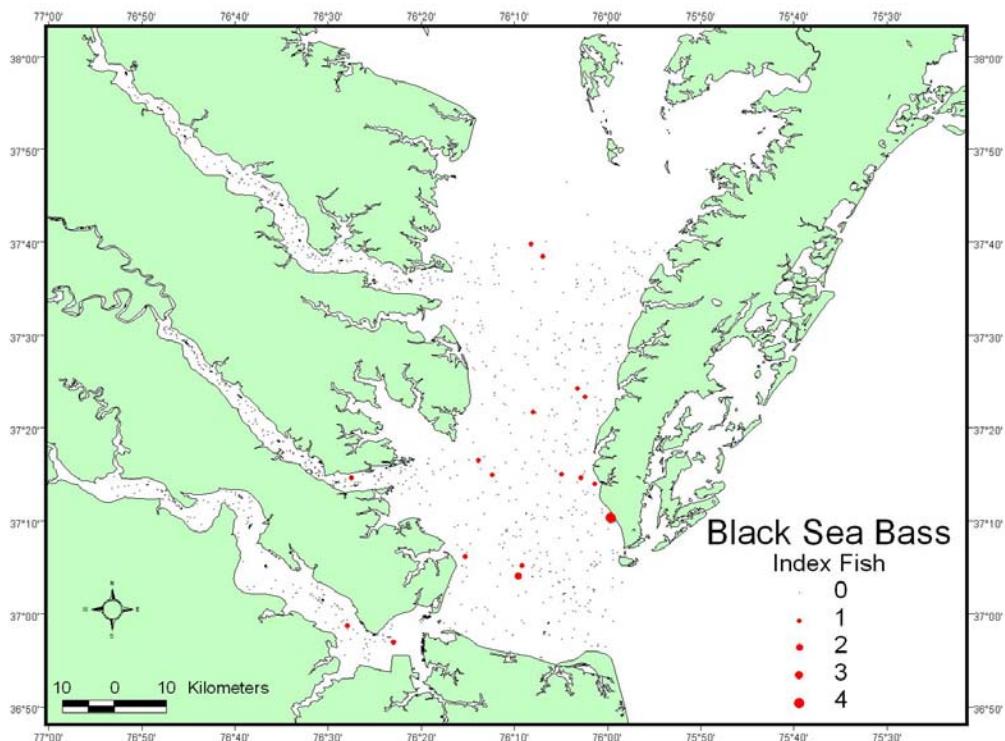

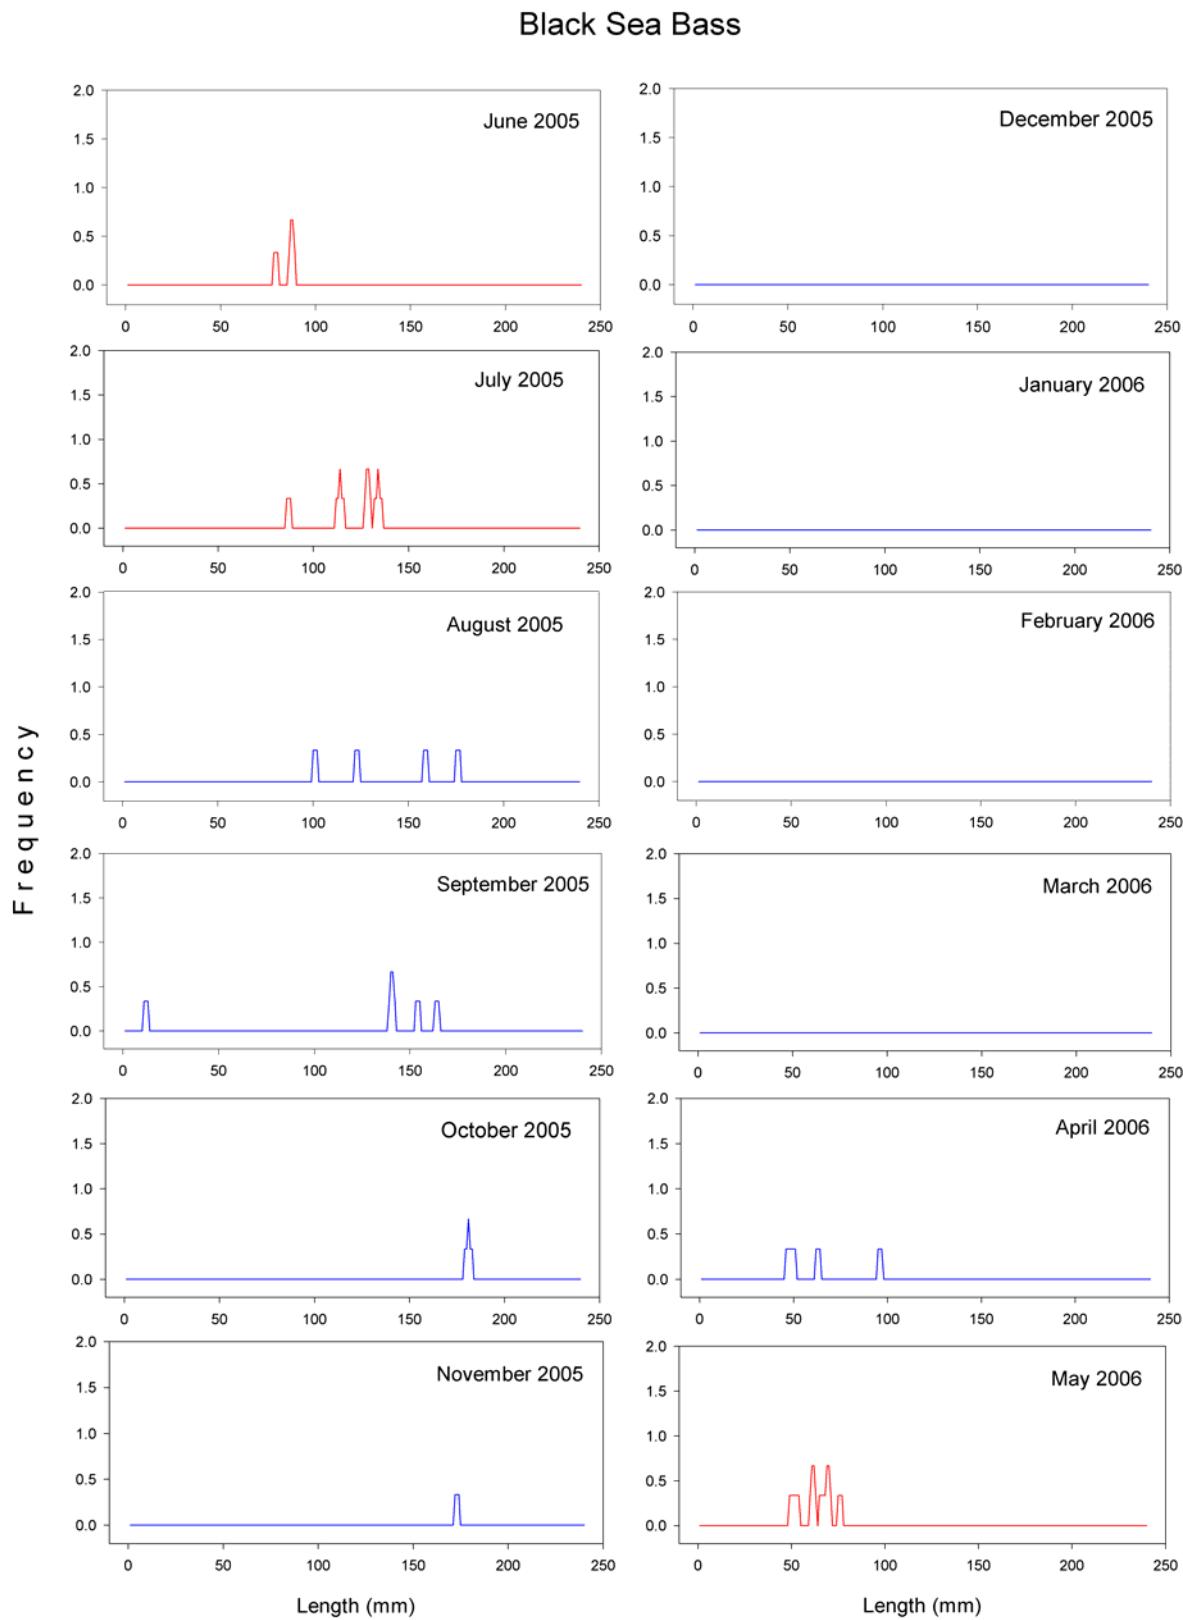

Figure 14. Size frequency of black sea bass by month for June 2005 to May 2006. Index months are shown in red.

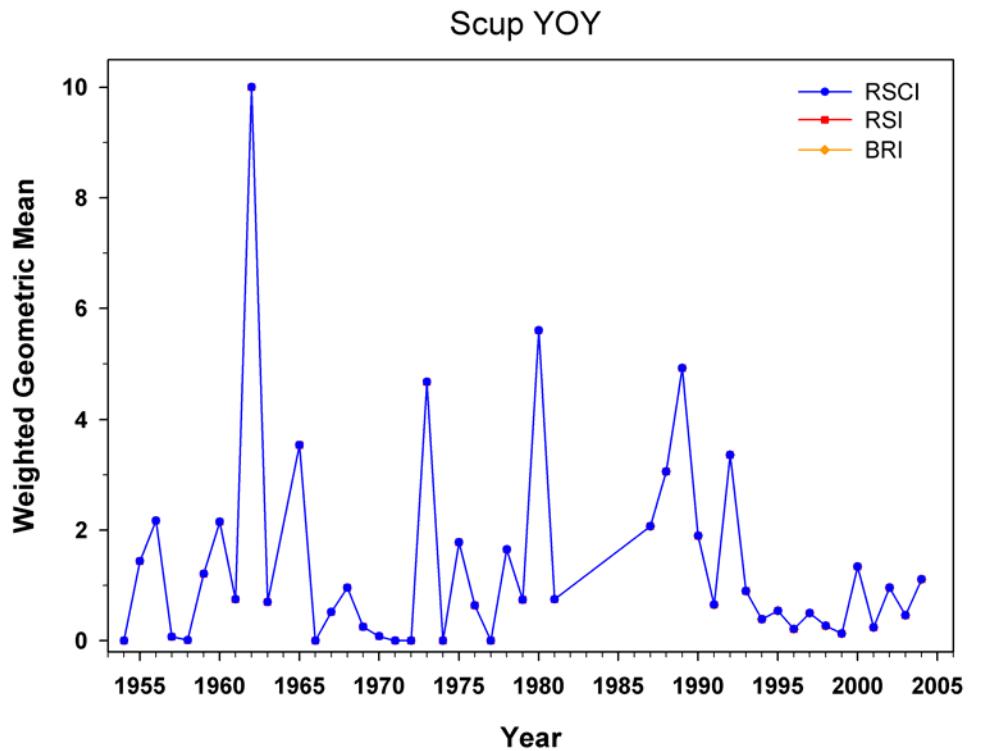

Figure 15. YOY scup random stratified (RSI), random stratified converted (RSCI), and Bay and fixed river station (BRI) indices (**top**), and distribution of YOY scup from June 2005 through May 2006 (**bottom**).

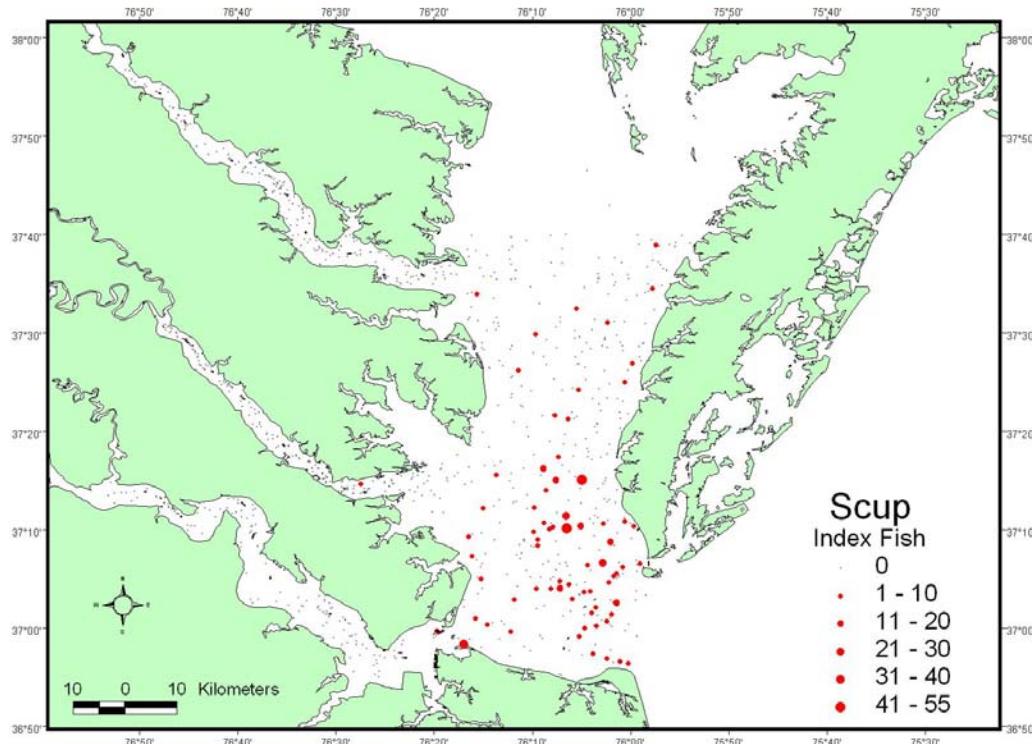

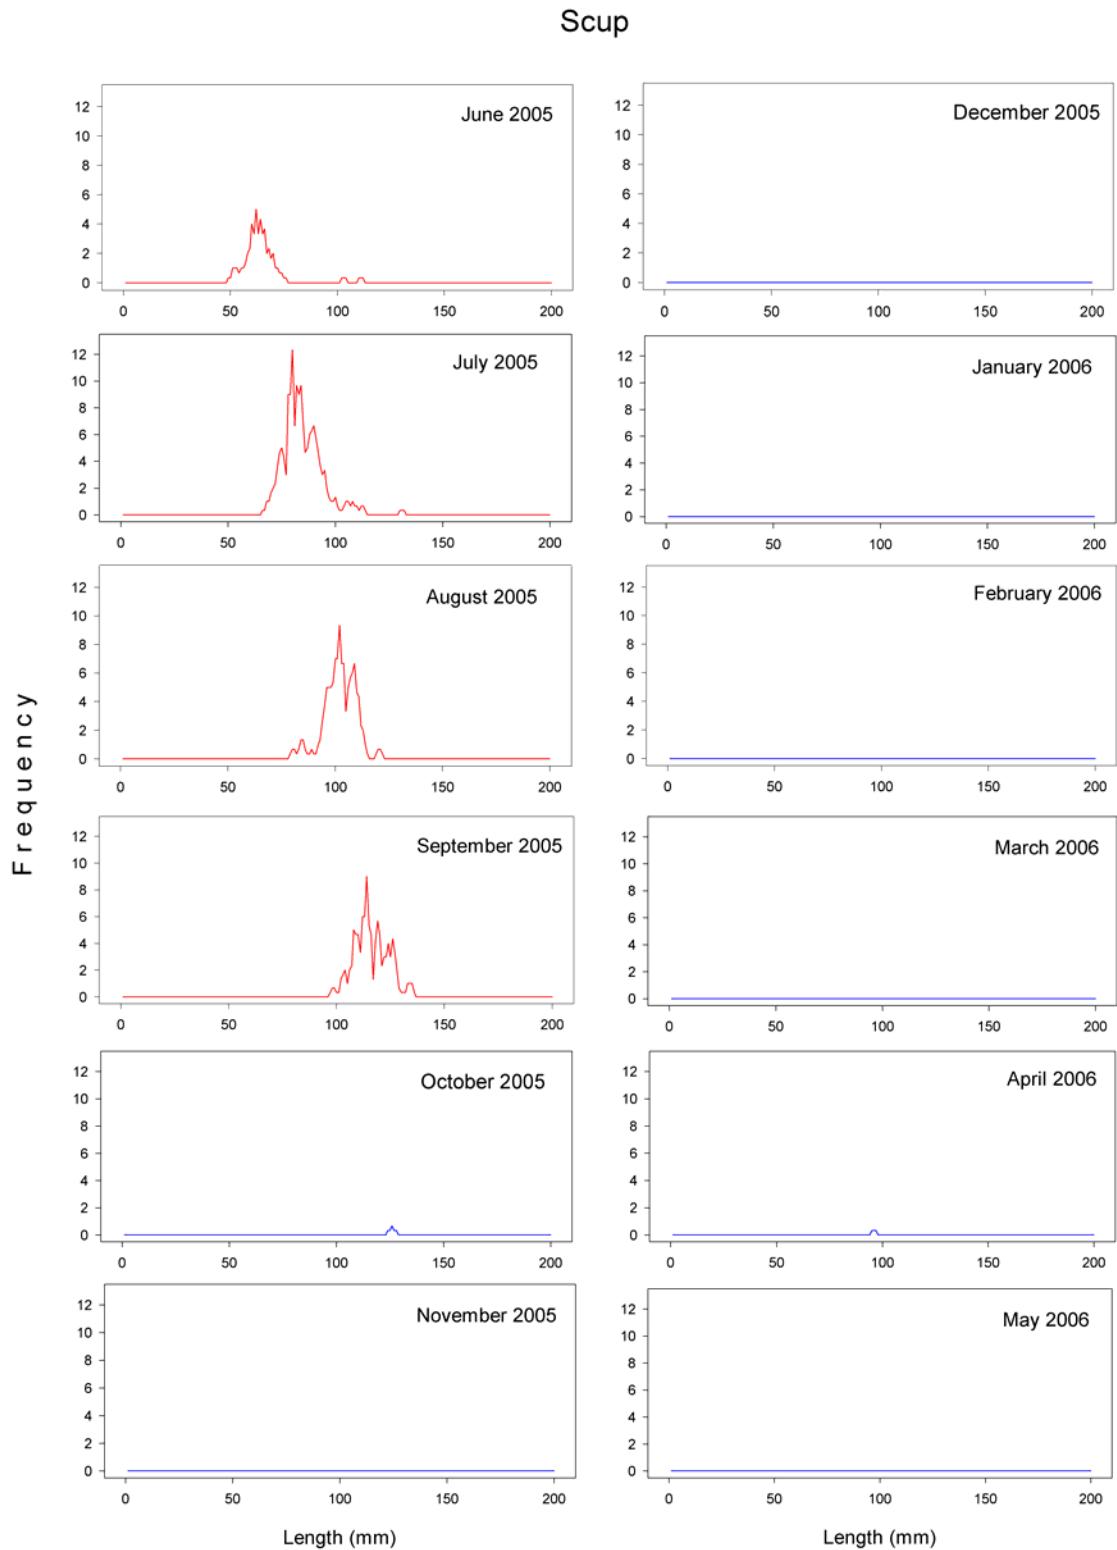

Figure 16. Size frequency of scup by month for June 2005 to May 2006. Index months are shown in red.

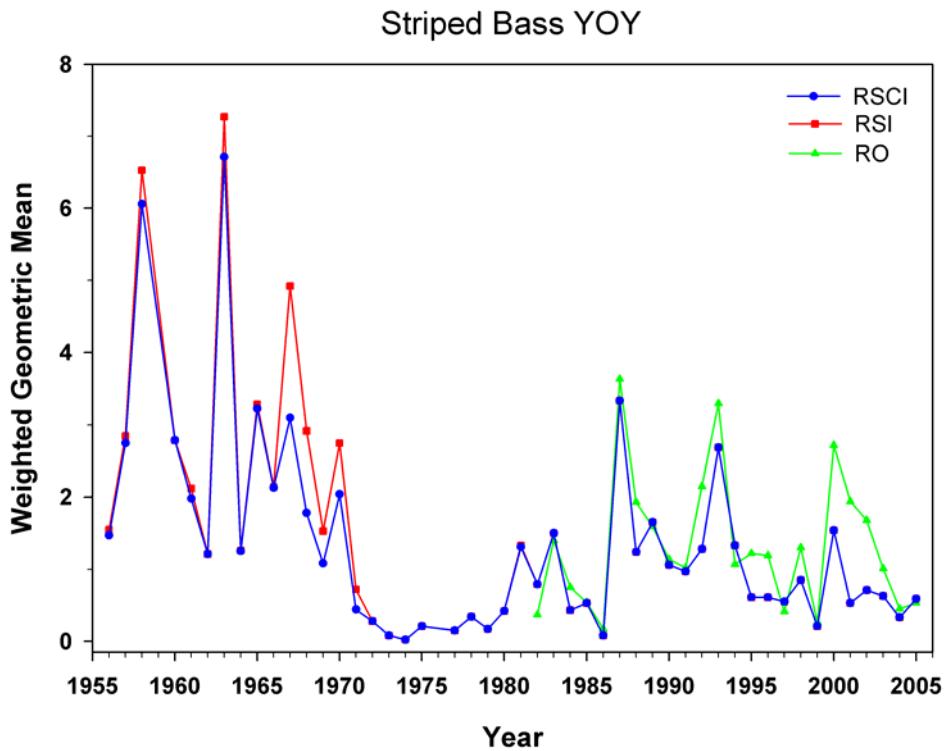

Figure 17. YOY striped bass random stratified (RSI), random stratified converted (RSCI), and fixed transect (Rivers Only-RO) indices (**top**), and distribution of YOY striped bass from June 2005 through May 2006 (**bottom**).

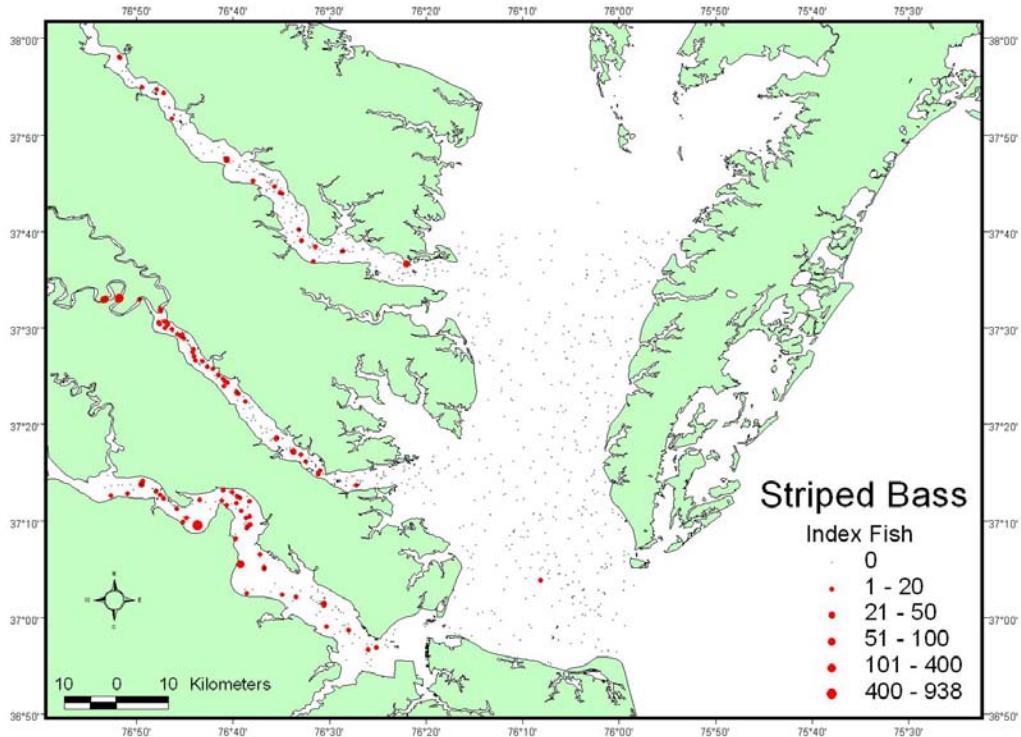

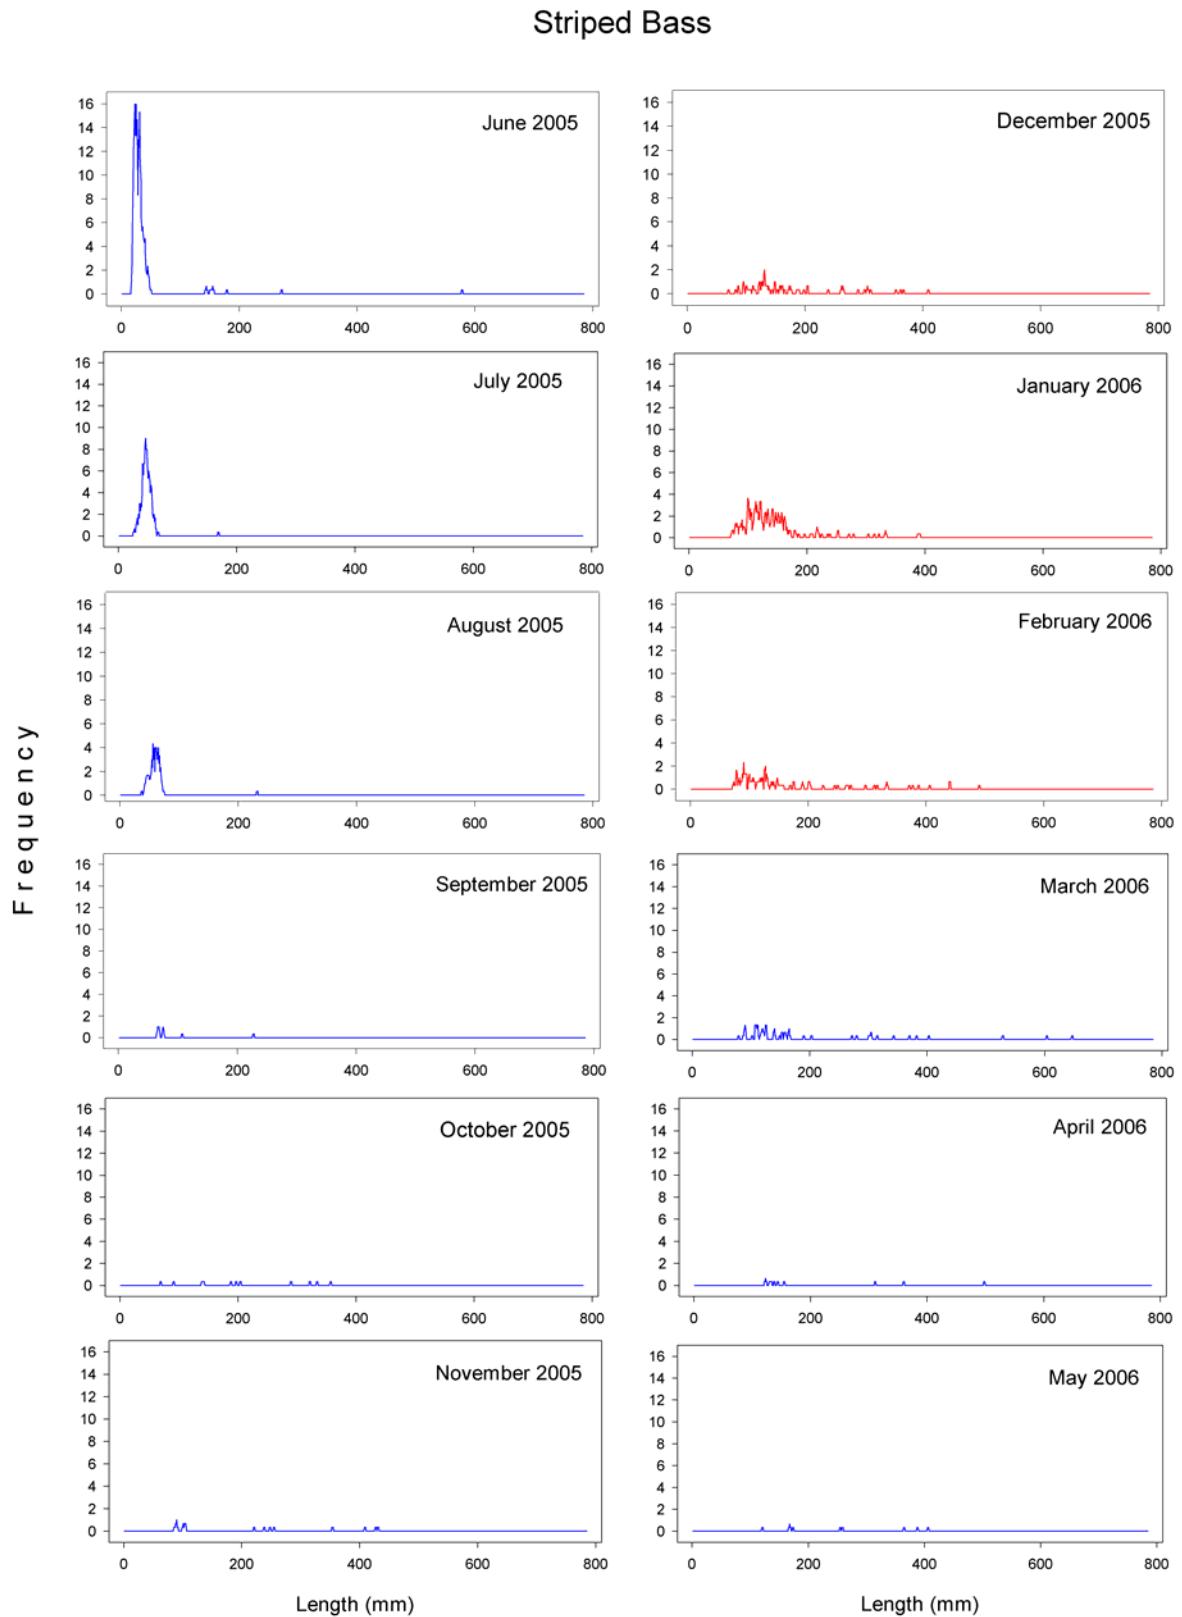

Figure 18. Size frequency of striped bass by month for June 2005 to May 2006. Index months are shown in red.

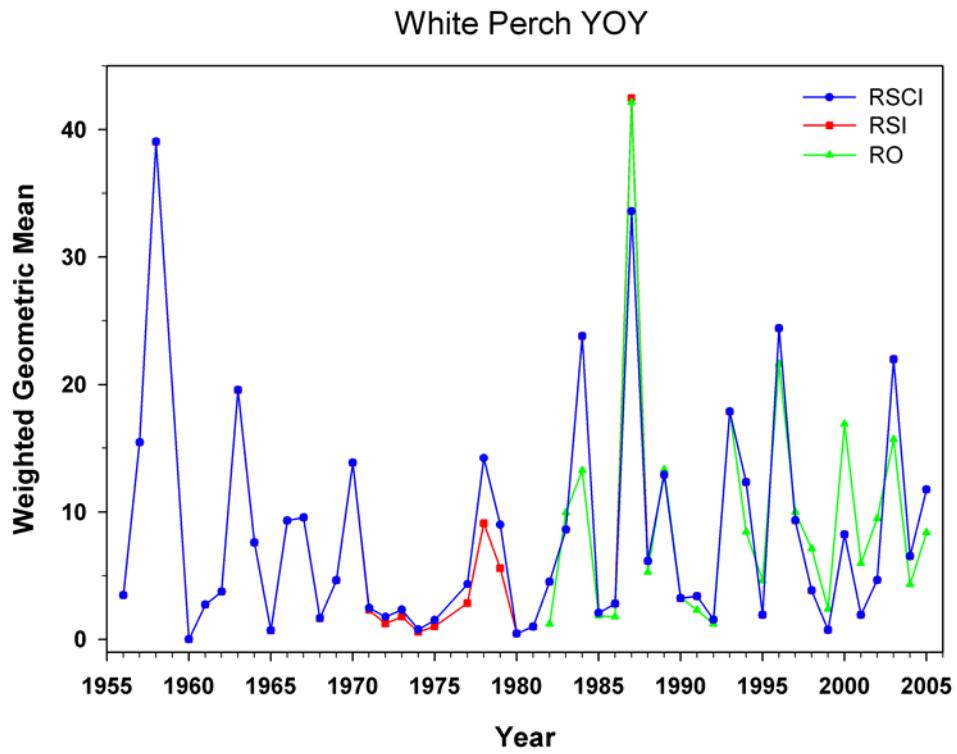

Figure 19. YOY white perch random stratified (RSI), random stratified converted (RSCI), and fixed transect (Rivers Only-RO) indices (**top**), and distribution of YOY white perch from June 2005 through May 2006 (**bottom**).

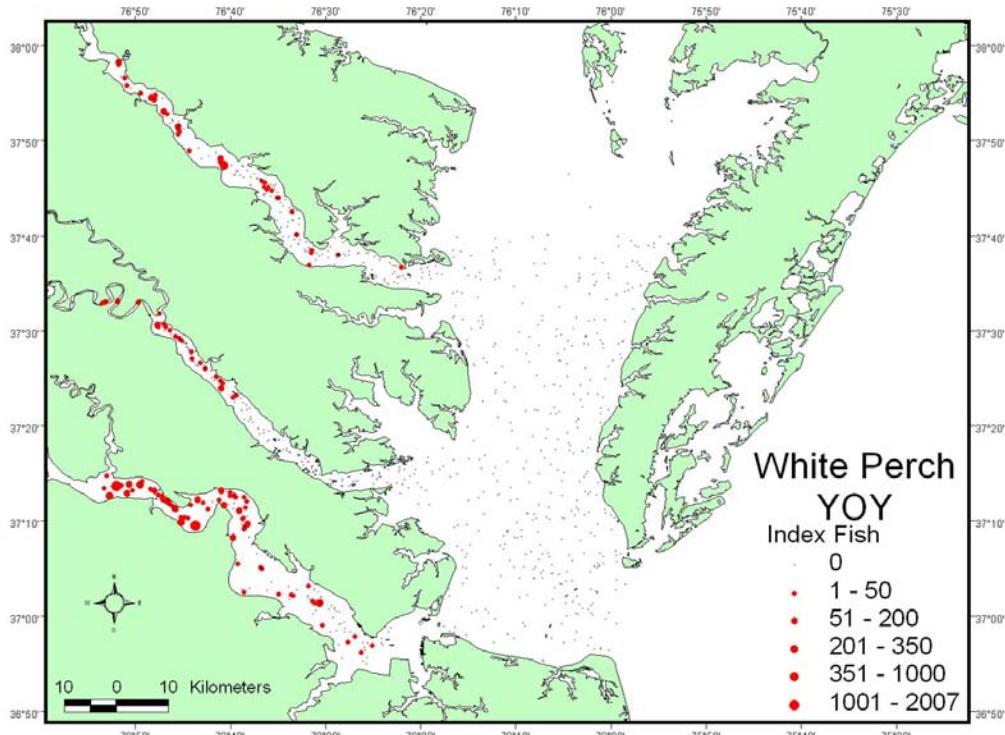

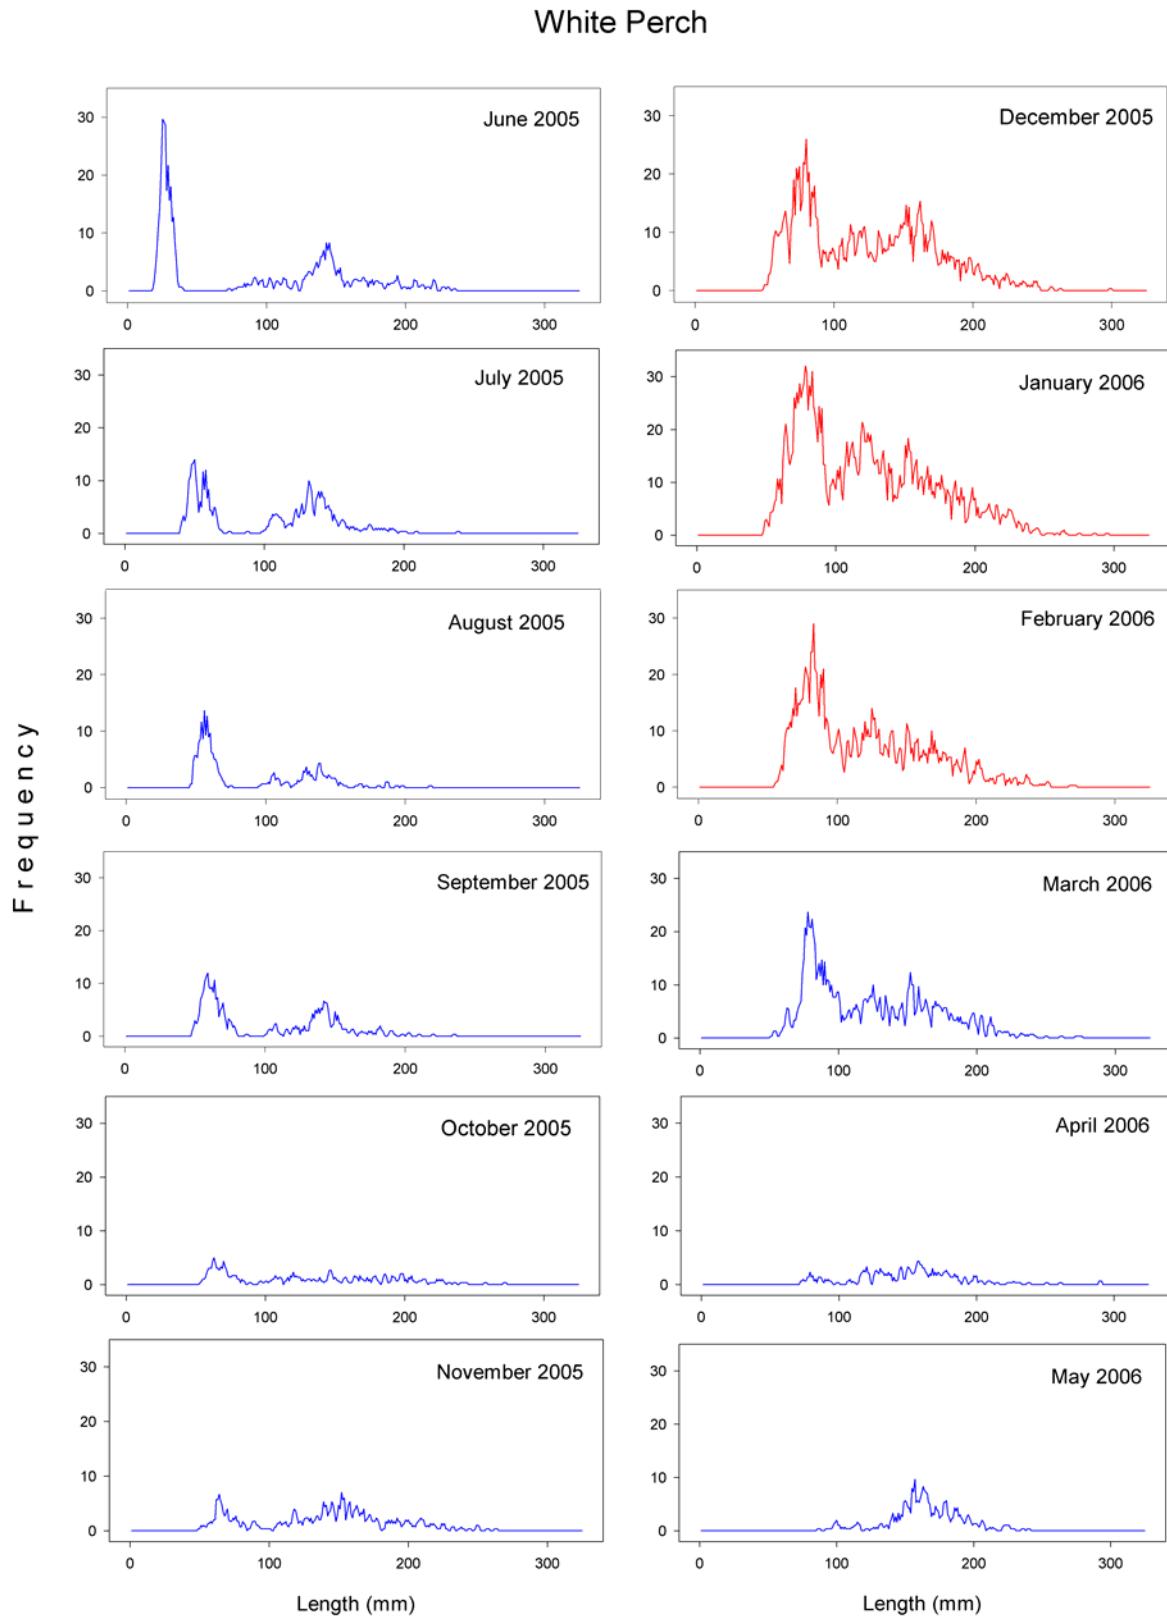

Figure 20. Size frequency of white perch by month for June 2005 to May 2006. Index months are shown in red.

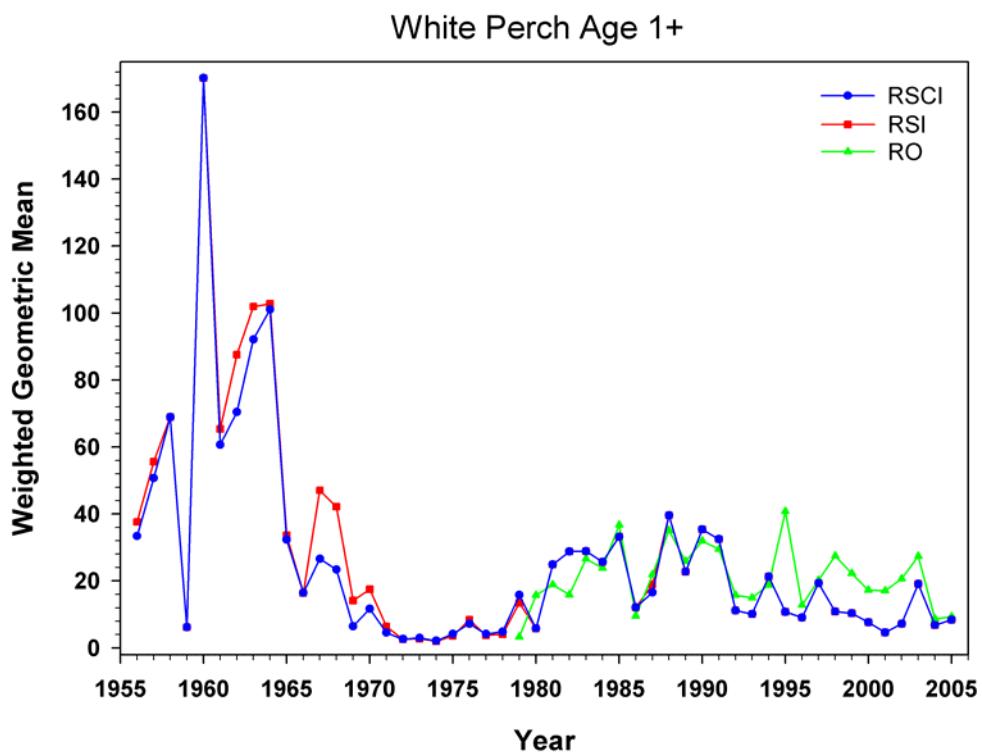

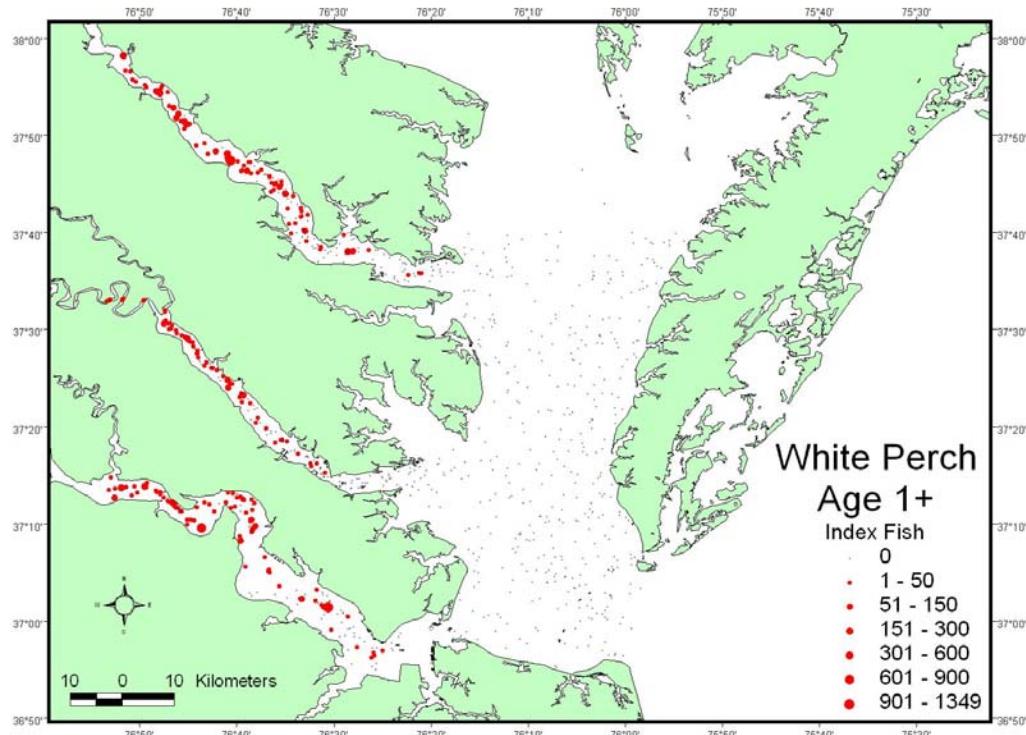

Figure 21. Age 1+ white perch random stratified (RSI), random stratified converted (RSCI), and fixed transect (Rivers Only-RO) indices (**top**), and distribution of age1+ white perch from June 2005 through May 2006 (**bottom**).

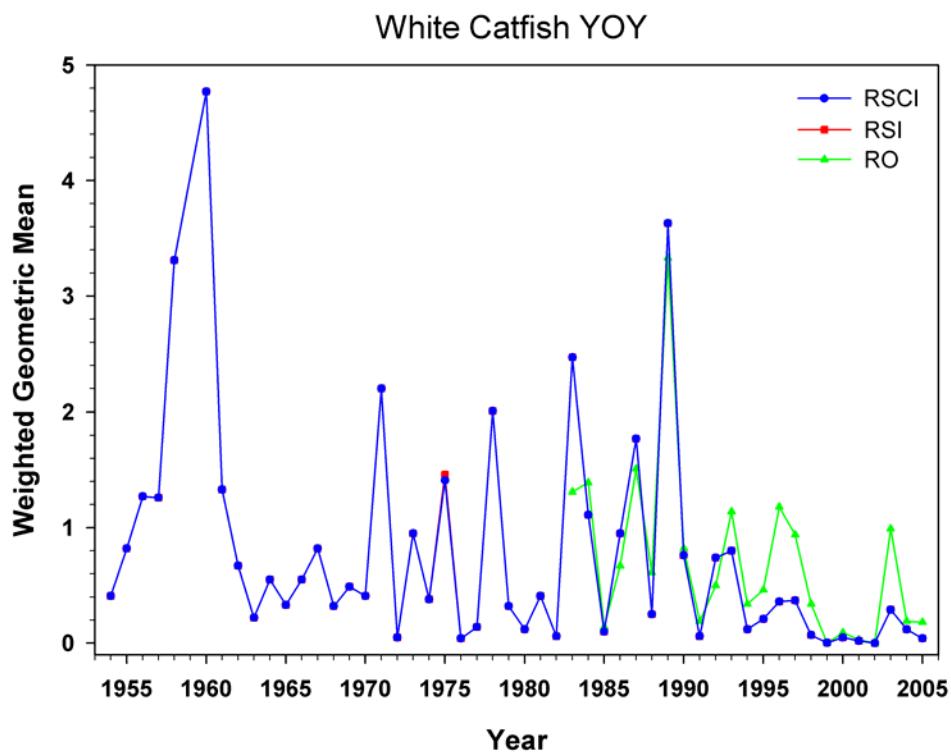

Figure 22. YOY white catfish random stratified (RSI), random stratified converted (RSCI), and fixed transect (Rivers Only-RO) indices (**top**), and distribution of YOY white catfish from June 2005 through May 2006 (**bottom**).

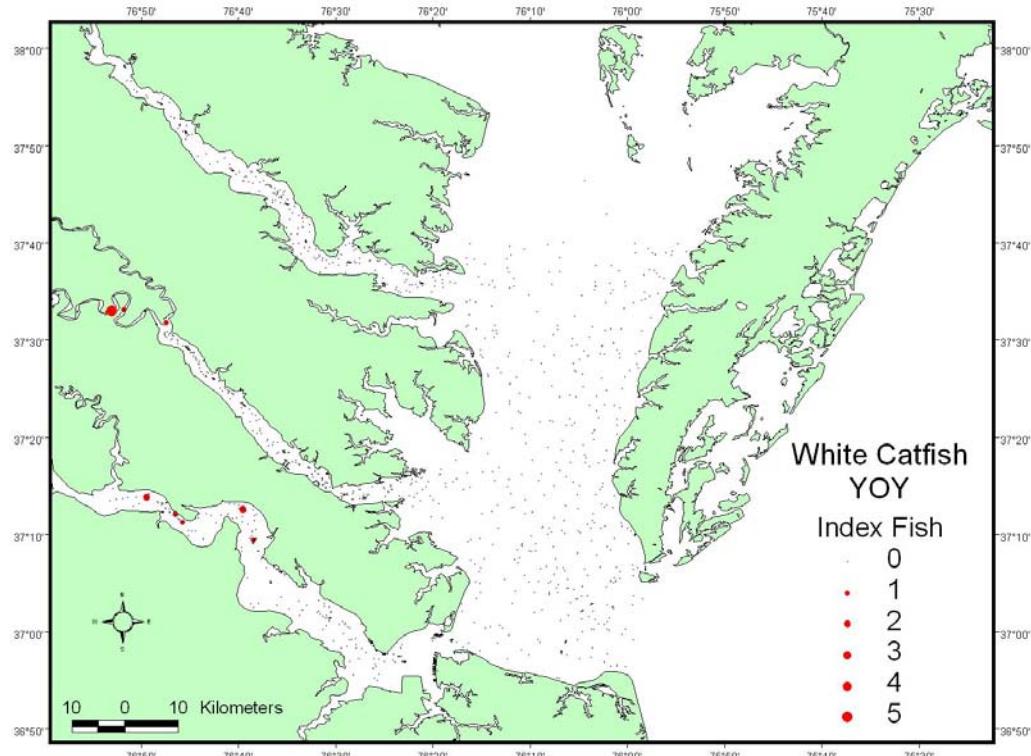

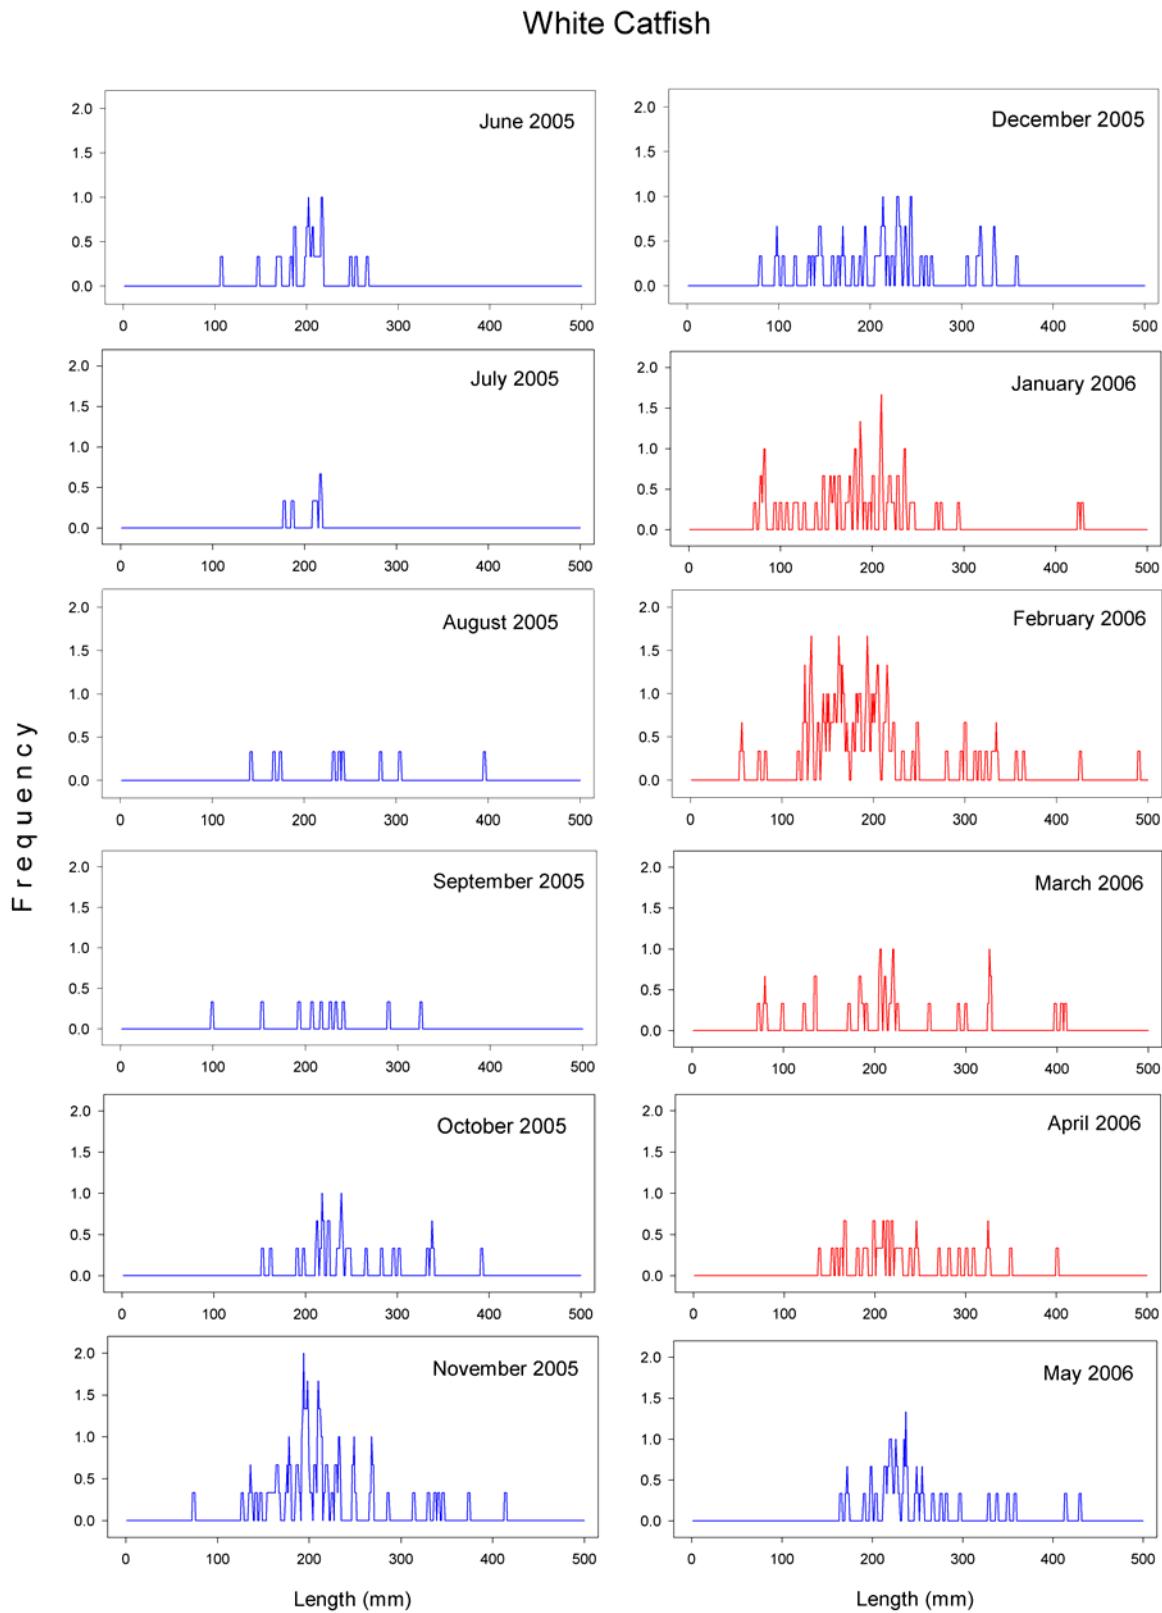

Figure 23. Size frequency of white catfish by month for June 2005 to May 2006. Index months are shown in red.

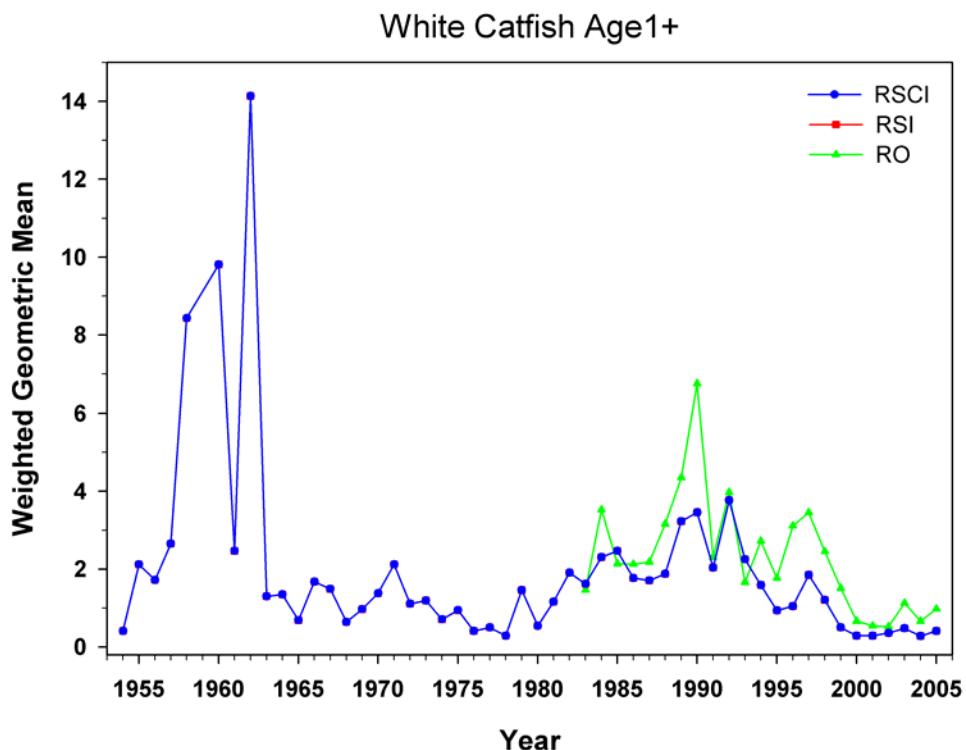

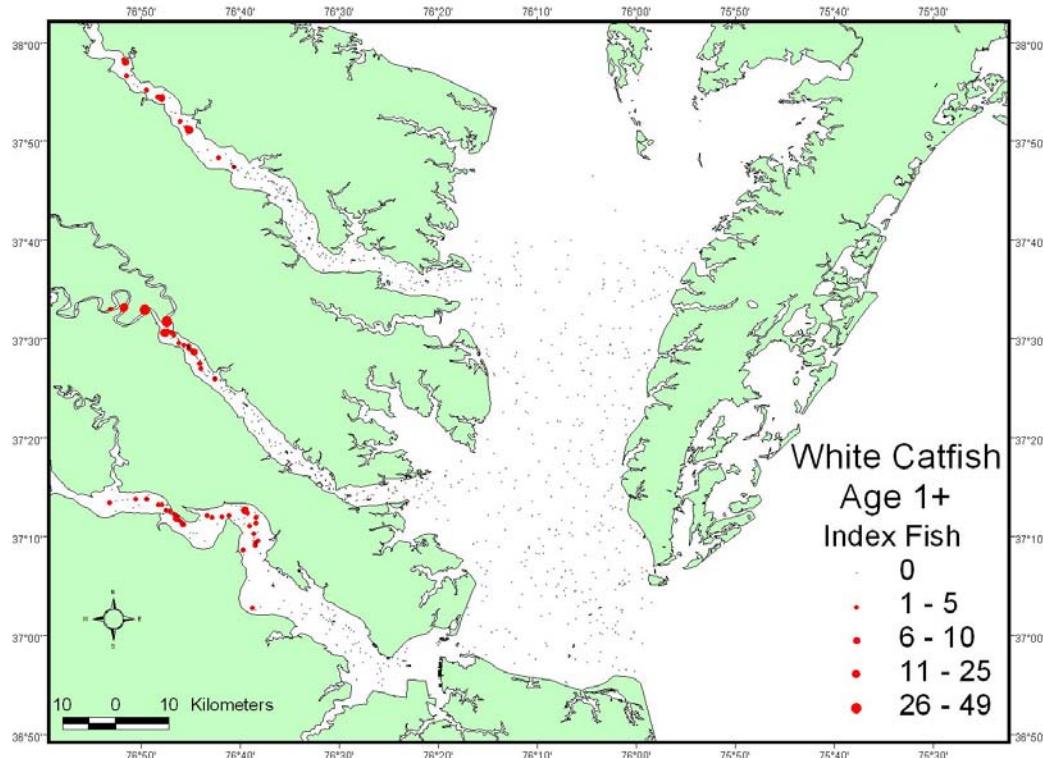

Figure 24. Age 1+ white catfish random stratified (RSI), random stratified converted (RSCI), and fixed transect (Rivers Only-RO) indices (**top**), and distribution of age 1+ white catfish from June 2005 through May 2006 (**bottom**).

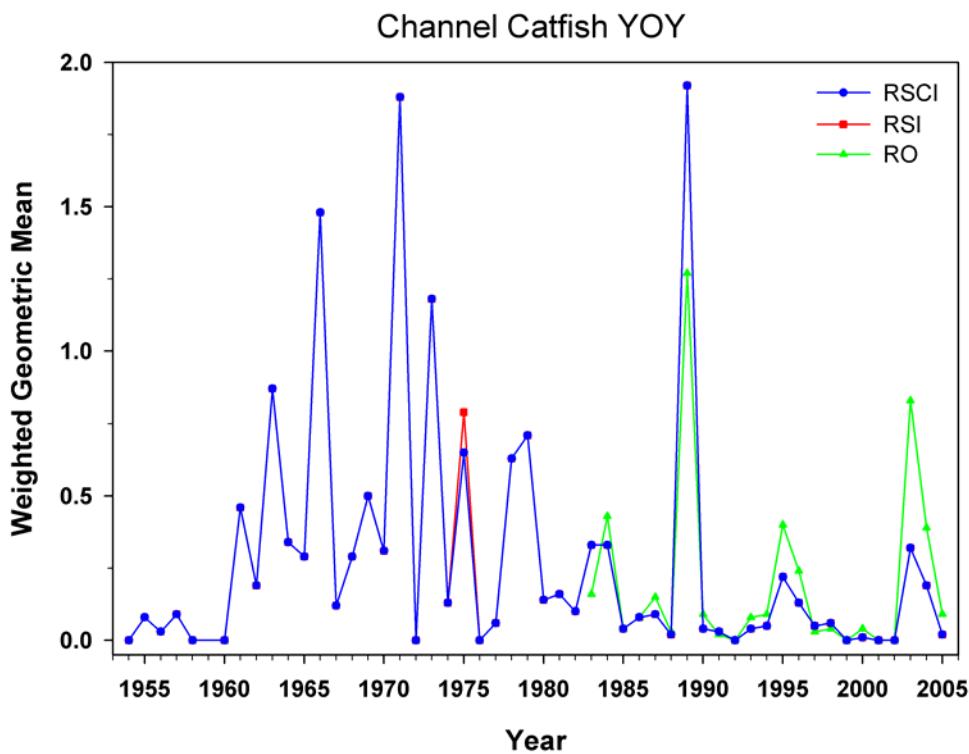

Figure 25. YOY channel catfish random stratified (RSI), random stratified converted (RSCI), and fixed transect (Rivers Only-RO) indices (**top**), and distribution of YOY channel catfish from June 2005 through May 2006 (**bottom**).

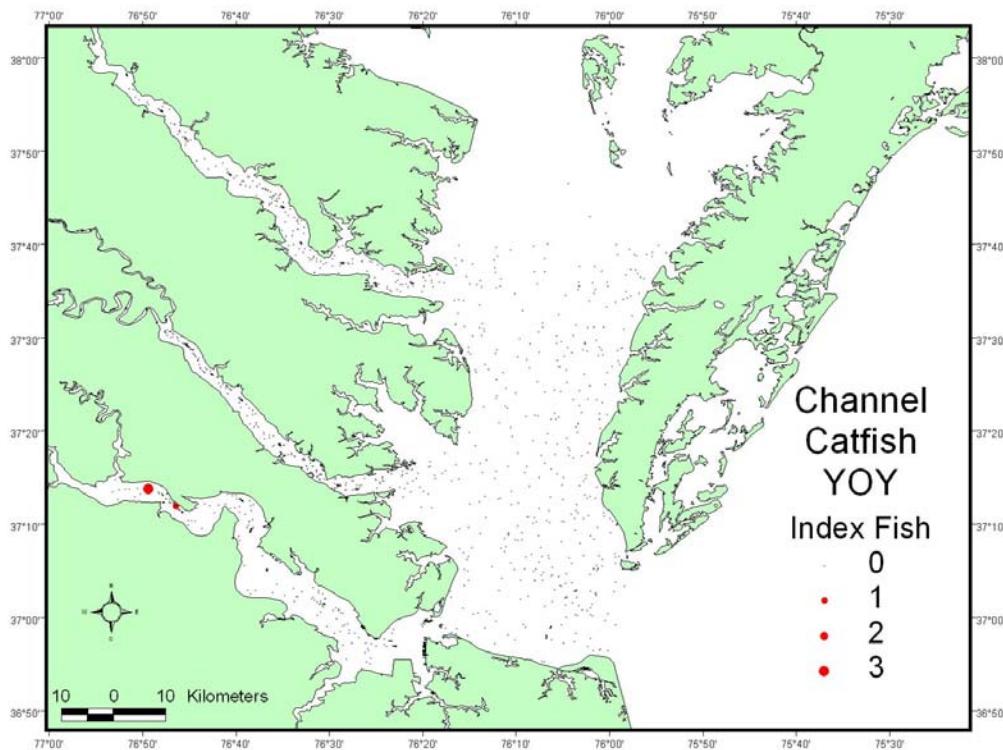

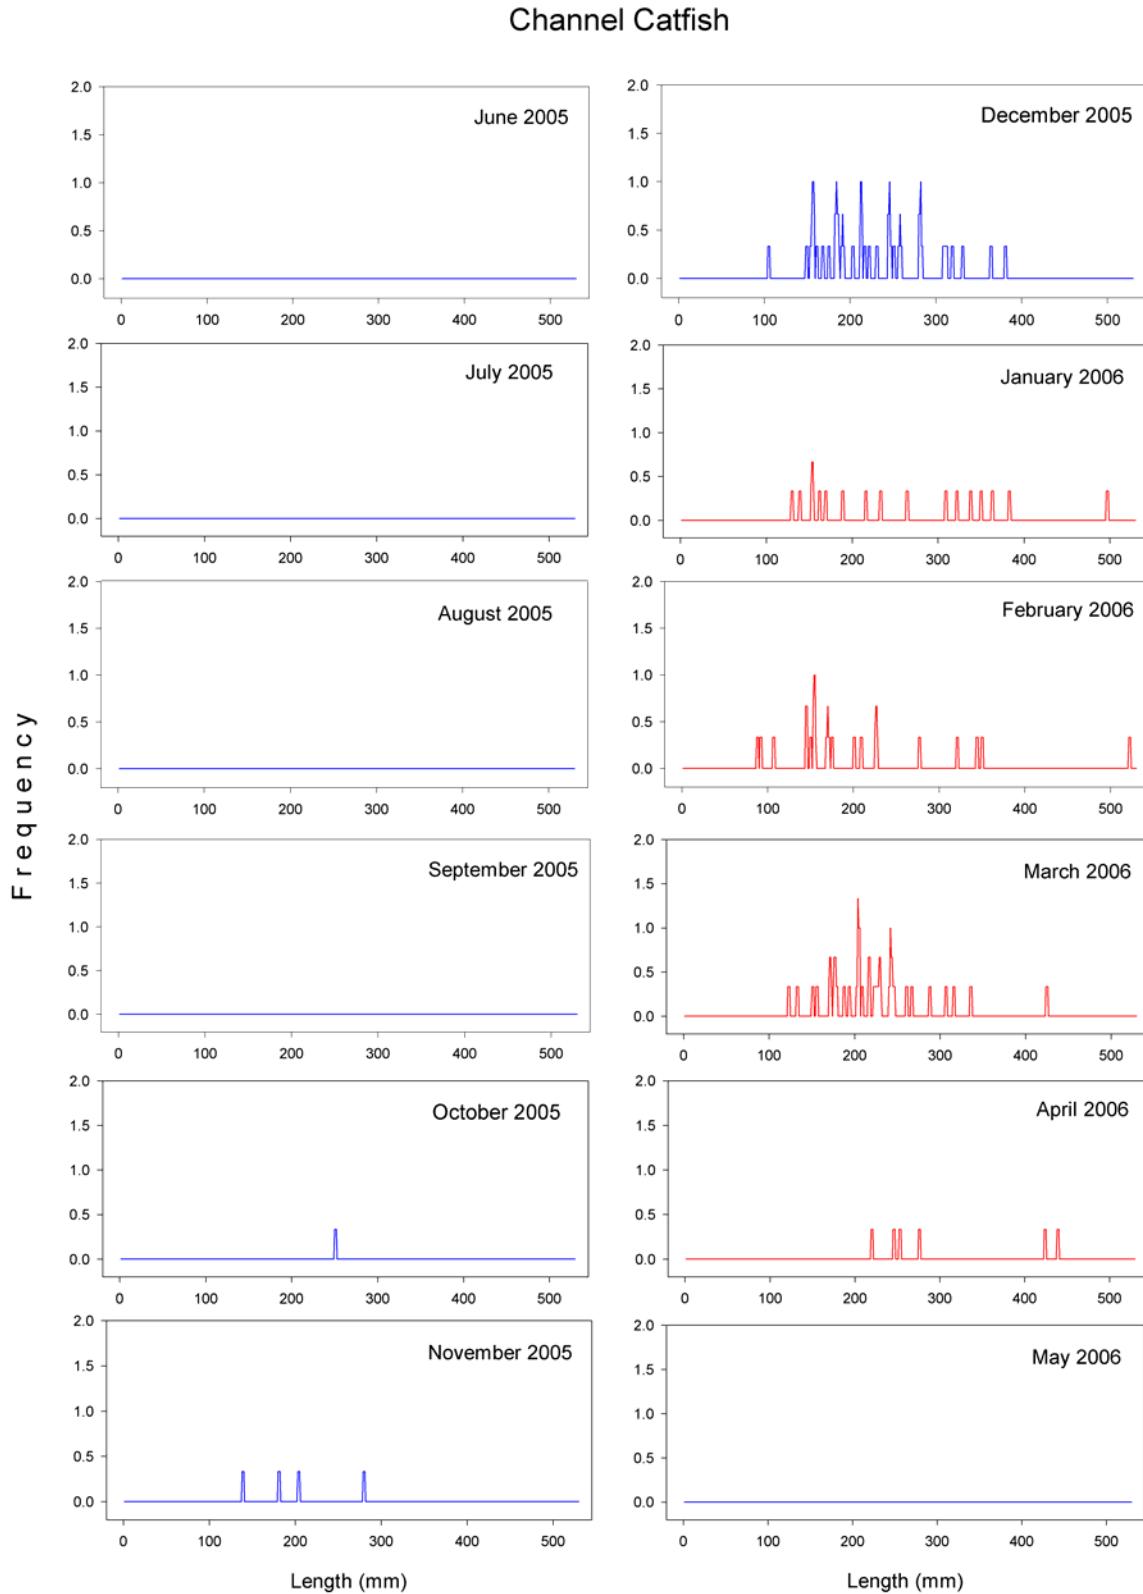

Figure 26. Size frequency of channel catfish by month for June 2005 to May 2006. Index months are shown in red.

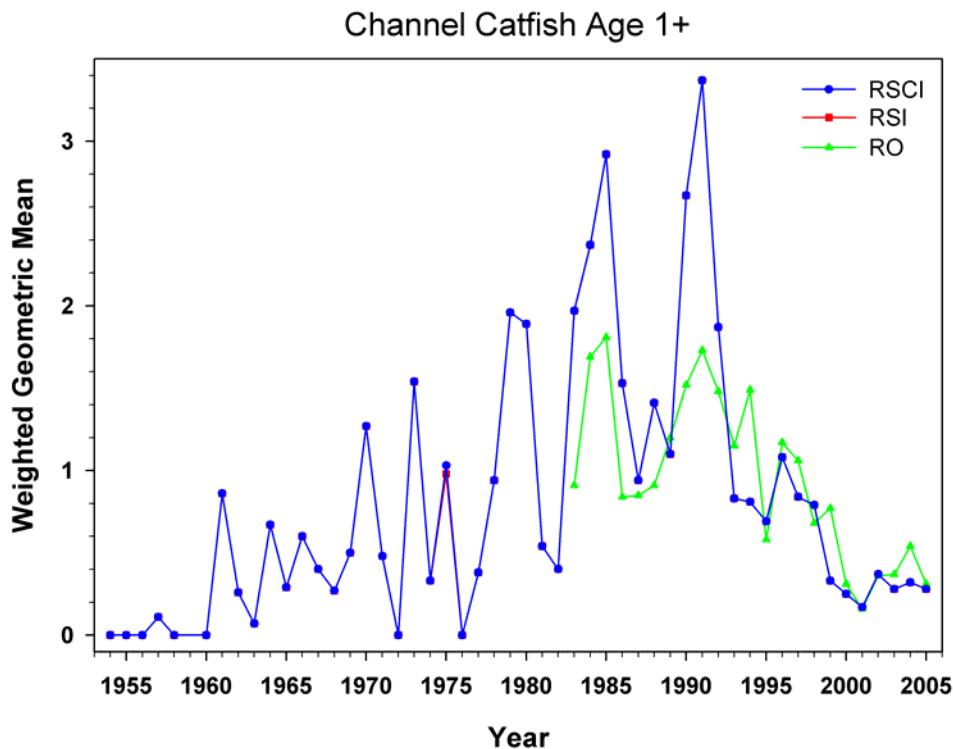

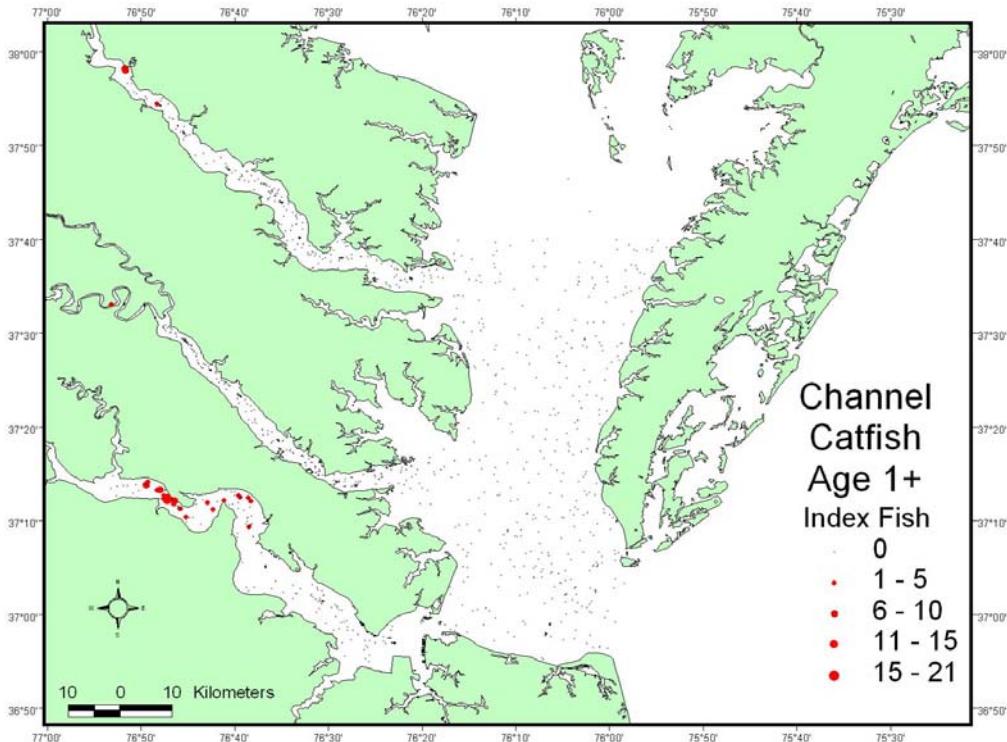

Figure 27. Age 1+ channel catfish random stratified (RSI), random stratified converted (RSCI), and fixed transect (Rivers Only-RO) indices (**top**), and distribution of age 1+ channel catfish from June 2005 through May 2006 (**bottom**).

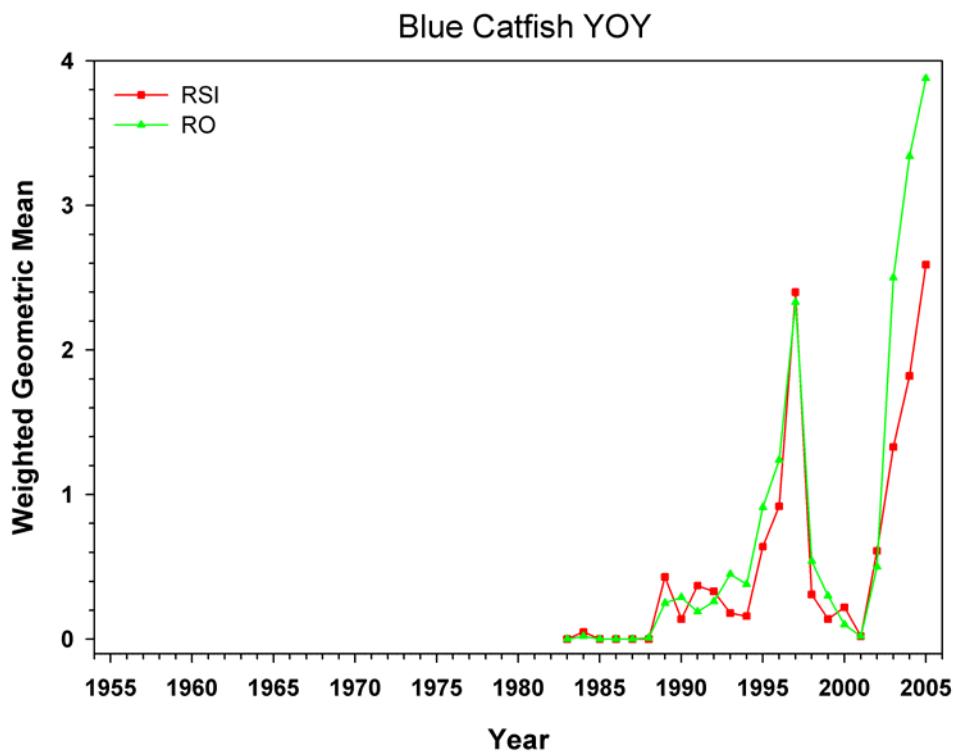

Figure 28. YOY blue catfish random stratified (RSI), and fixed transect (Rivers Only-RO) indices (top), and distribution of YOY blue catfish from June 2005 through May 2006 (bottom).

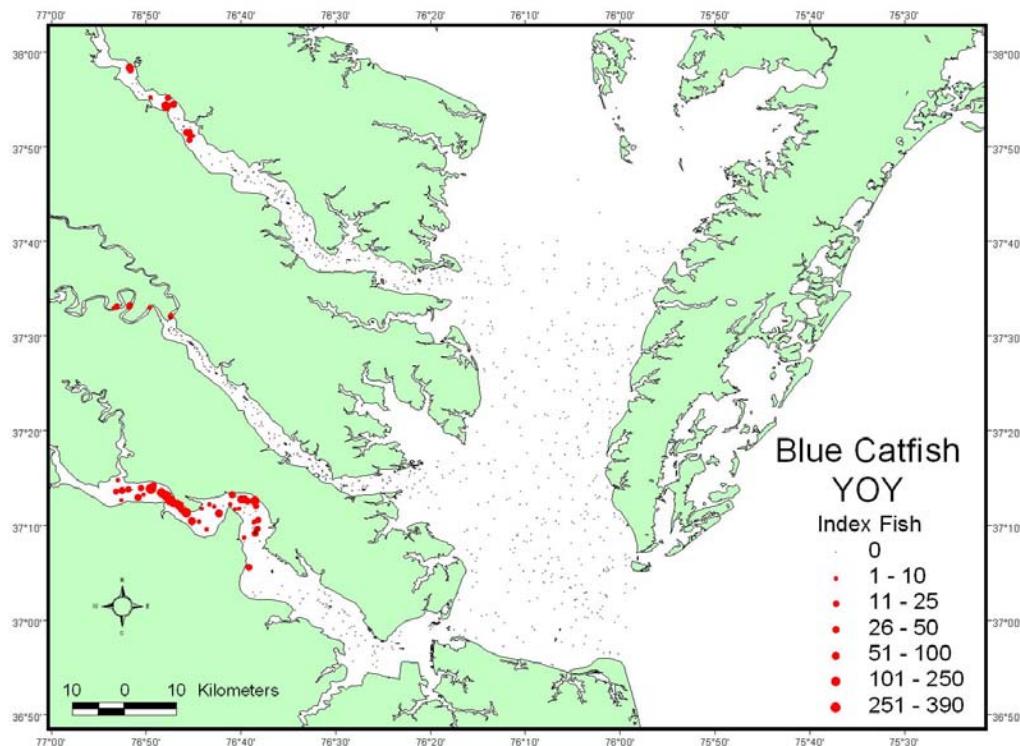

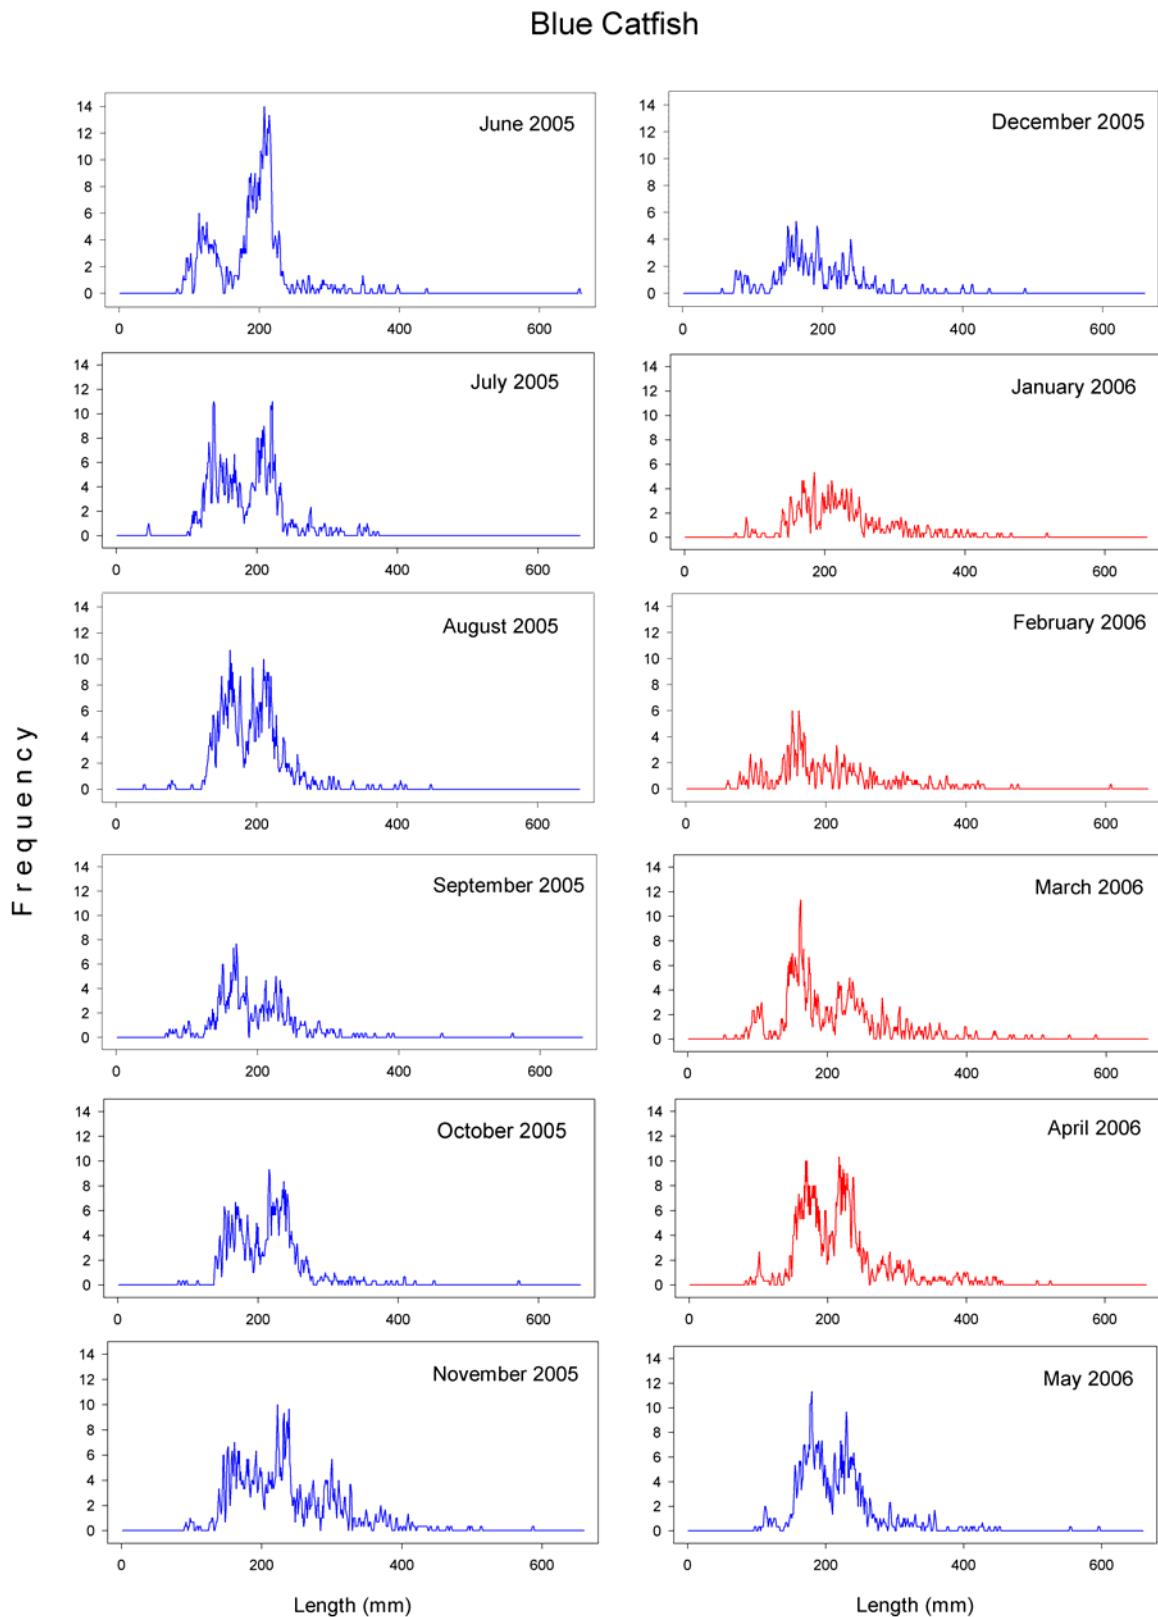

Figure 29. Size frequency of blue catfish by month for June 2005 to May 2006. Index months are shown in red.

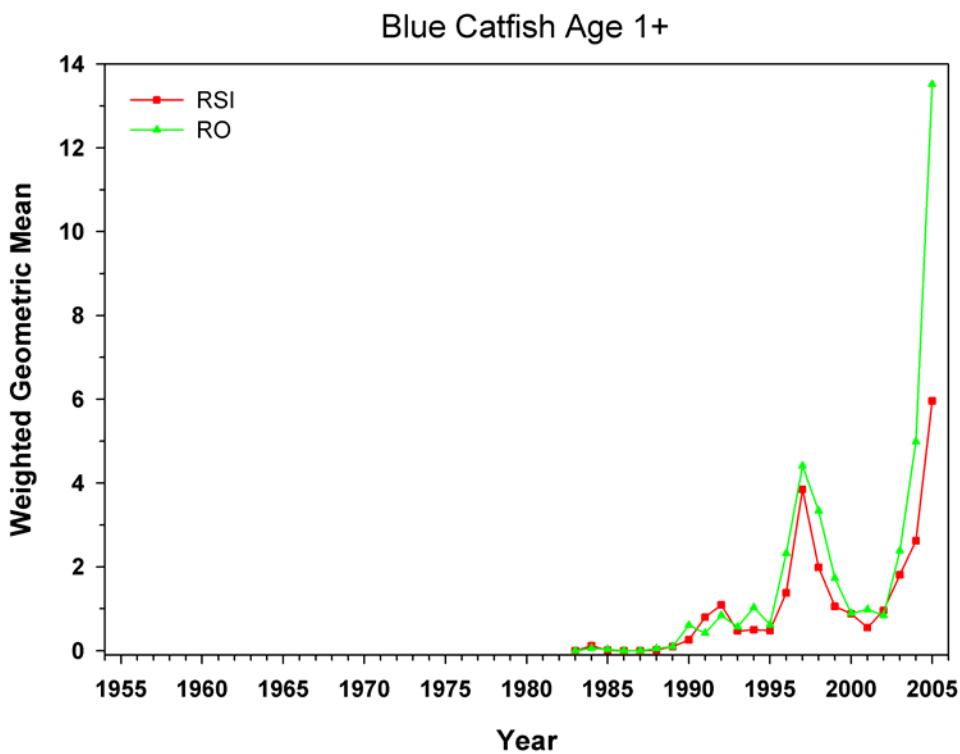

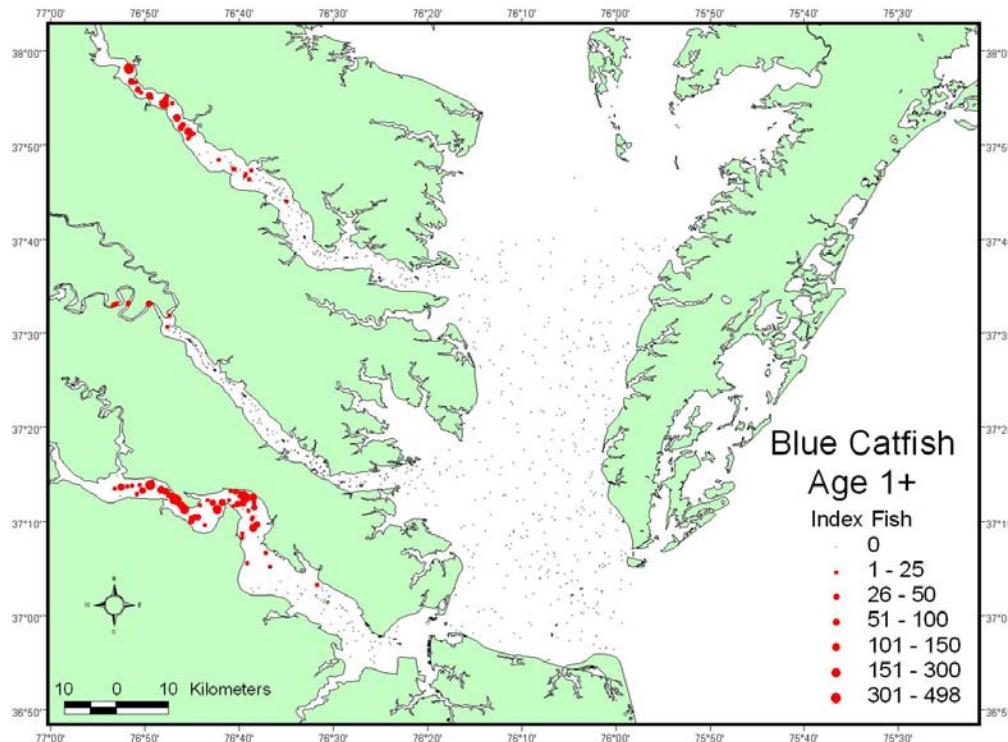

Figure 30. Age 1+ blue catfish random stratified (RSI), and fixed transect (Rivers Only-RO) indices (**top**), and distribution of age 1+ blue catfish from June 2005 through May 2006 (**bottom**).

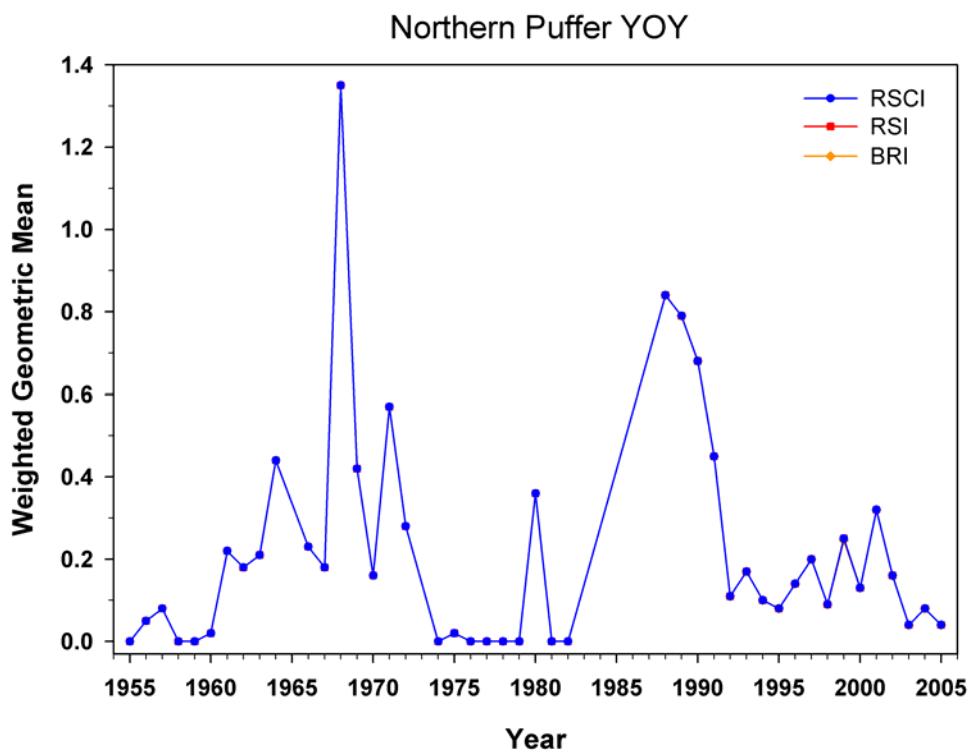

Figure 31. YOY northern puffer random stratified (RSI), random stratified converted (RSCI), and Bay and fixed river station (BRI) indices (**top**), and distribution of YOY northern puffer from June 2005 through May 2006 (**bottom**).

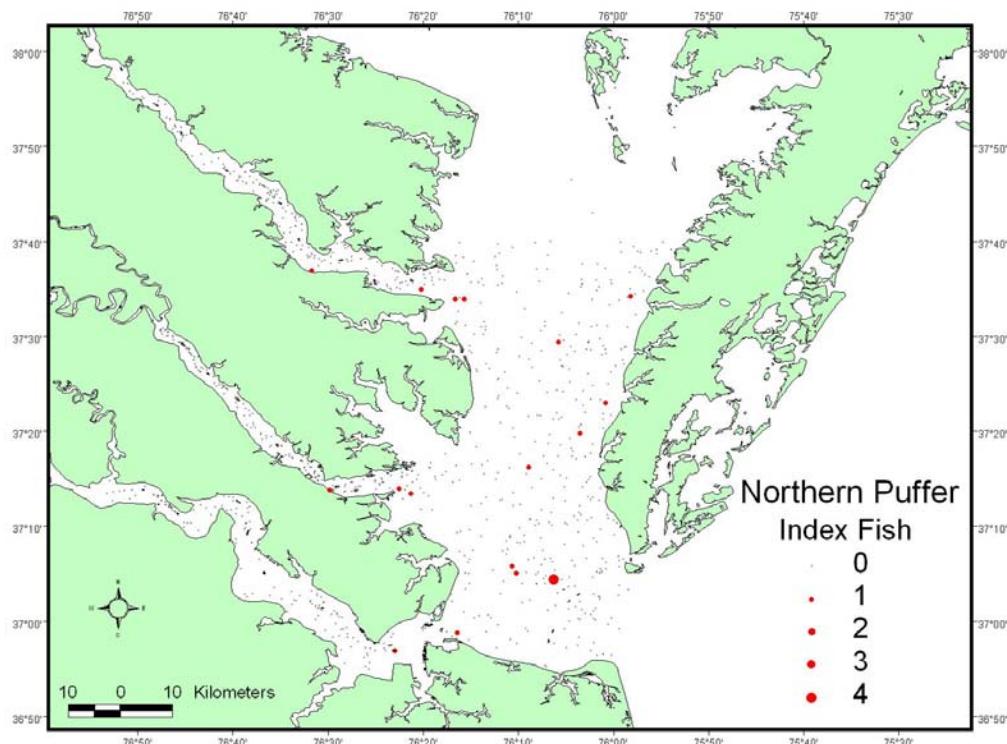

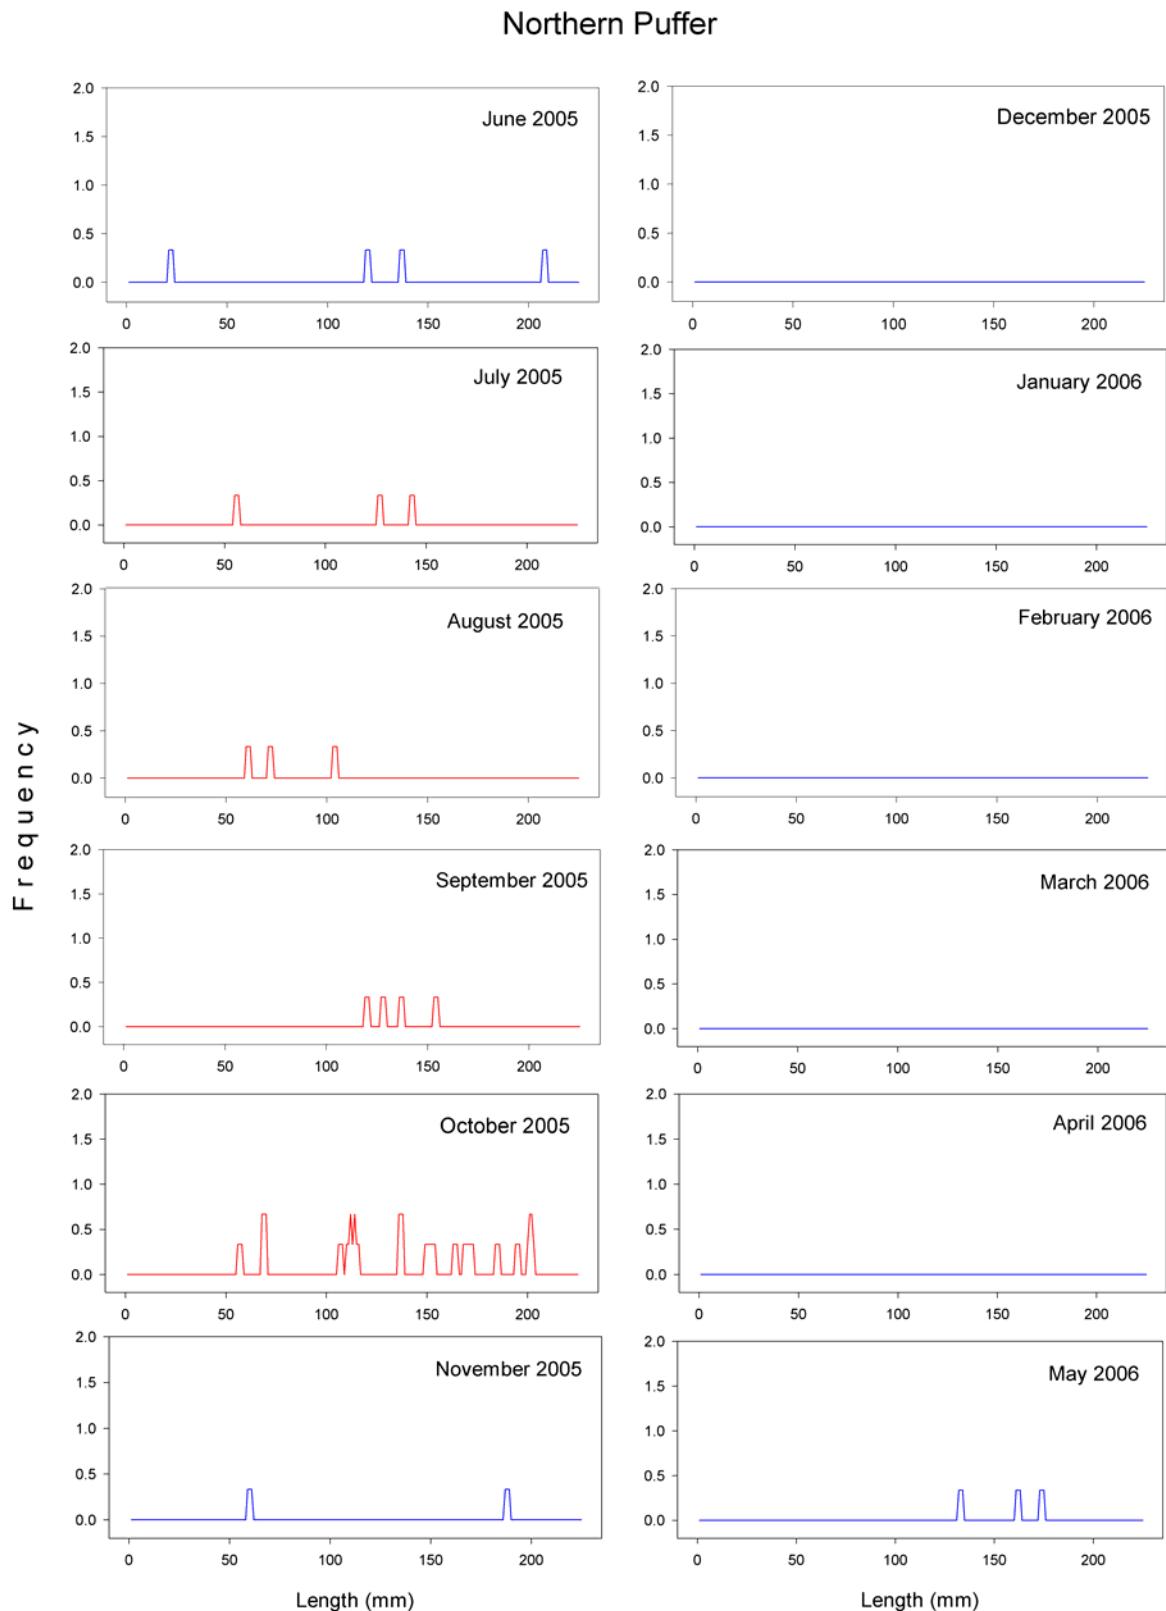

Figure 32. Size frequency of northern puffer by month for June 2005 to May 2006. Index months are shown in red.

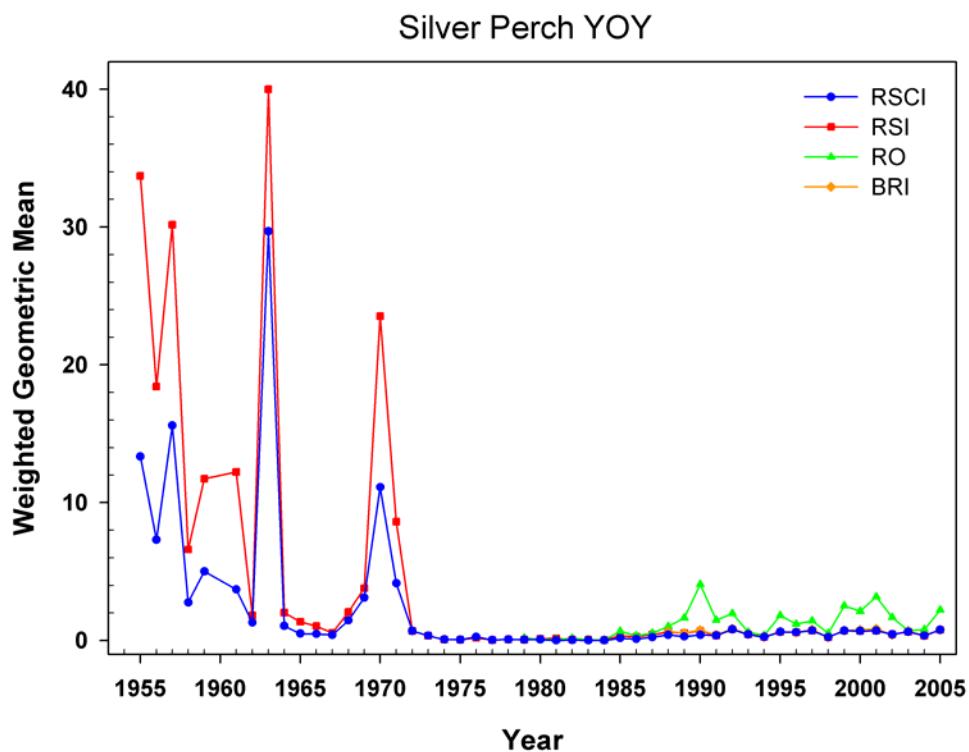

Figure 33. YOY silver perch random stratified (RSI), random stratified converted (RSCI), fixed transect (Rivers Only-RO), and Bay and fixed river station (BRI) indices (**top**), and distribution of YOY silver perch from June 2005 through May 2006 (**bottom**).

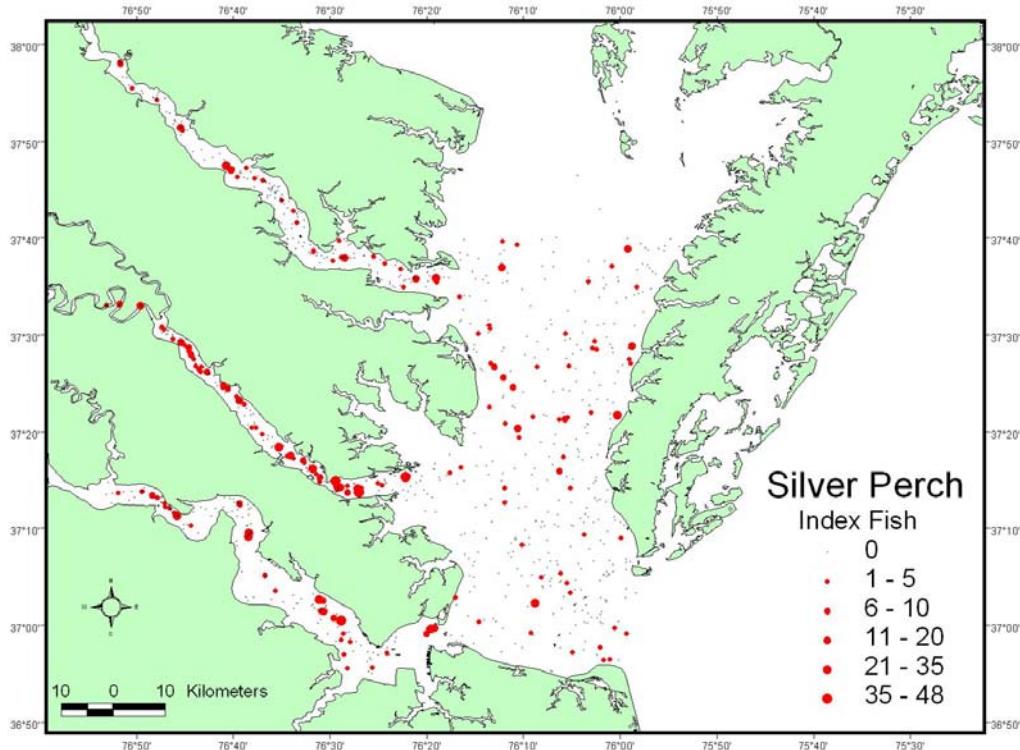

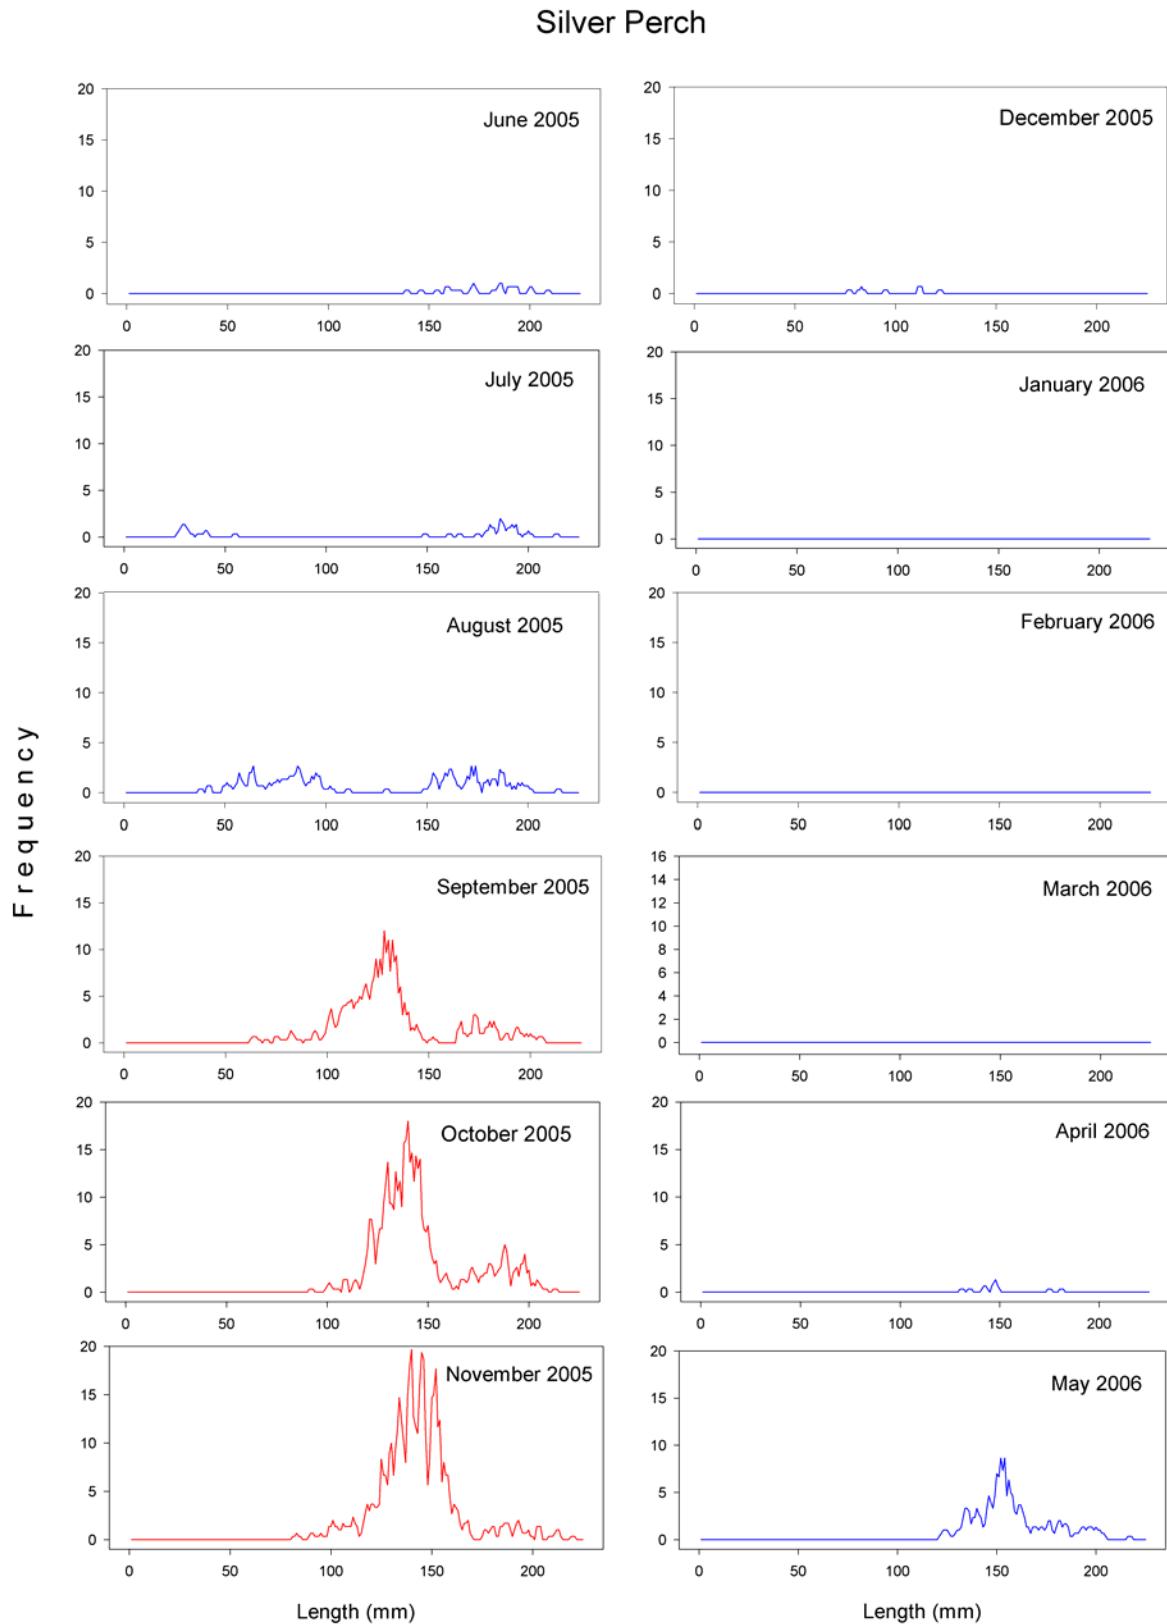

Figure 34. Size frequency of silver perch by month for June 2005 to May 2006. Index months are shown in red.

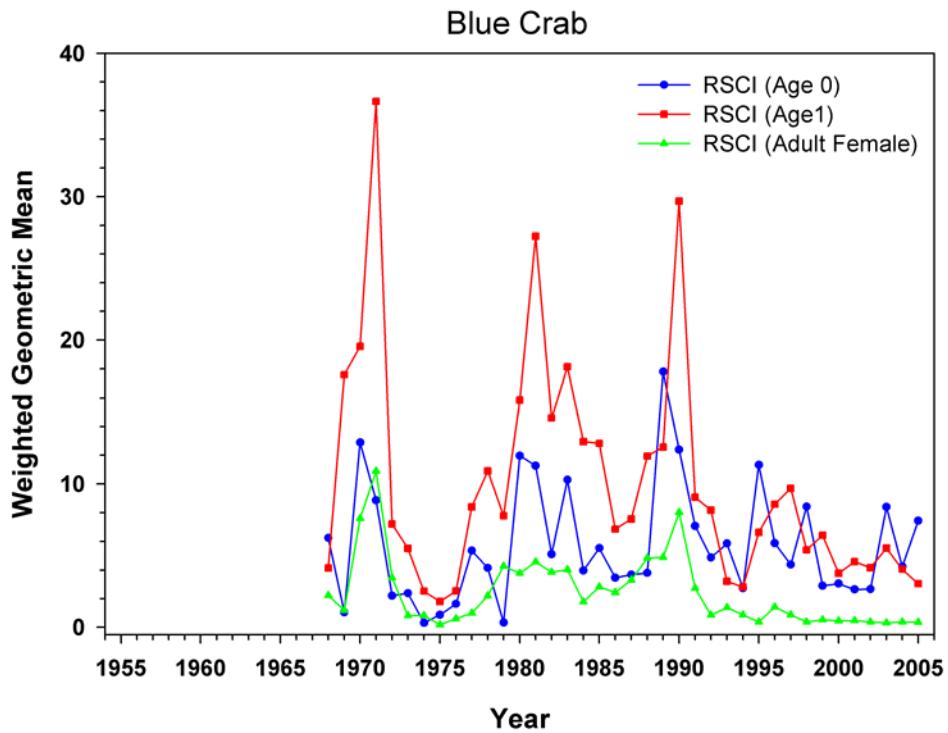

Figure 35. Age 0 (YOY), Age 1+, and adult female blue crab random stratified converted (RSCI) indices.

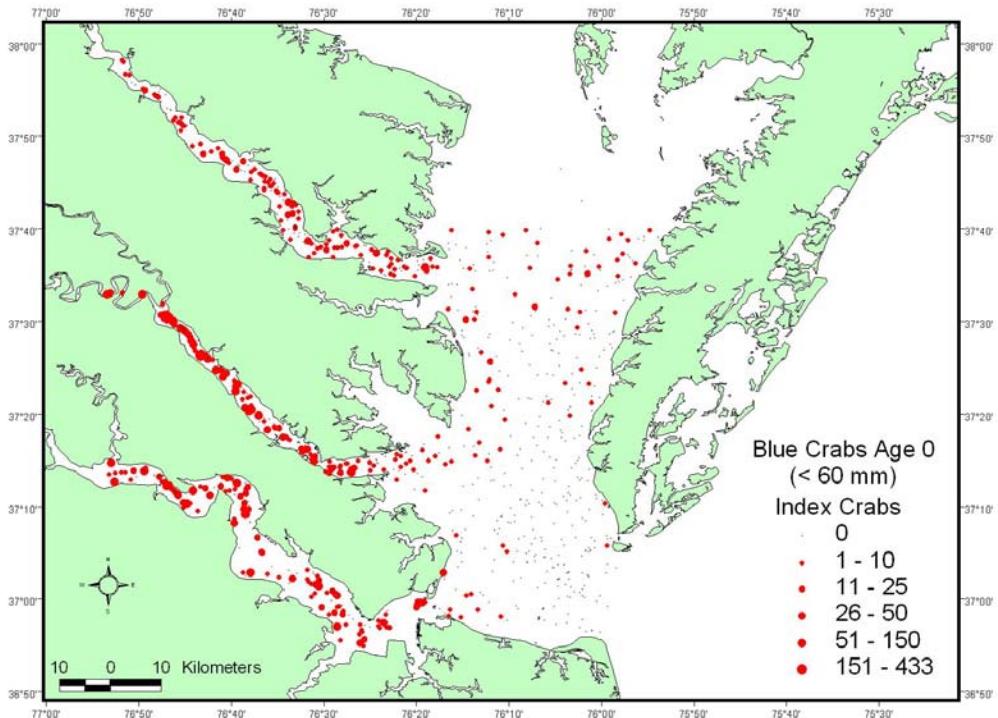

Figure 36. Distribution of Age 0 blue crabs from June 2005 through May 2006.

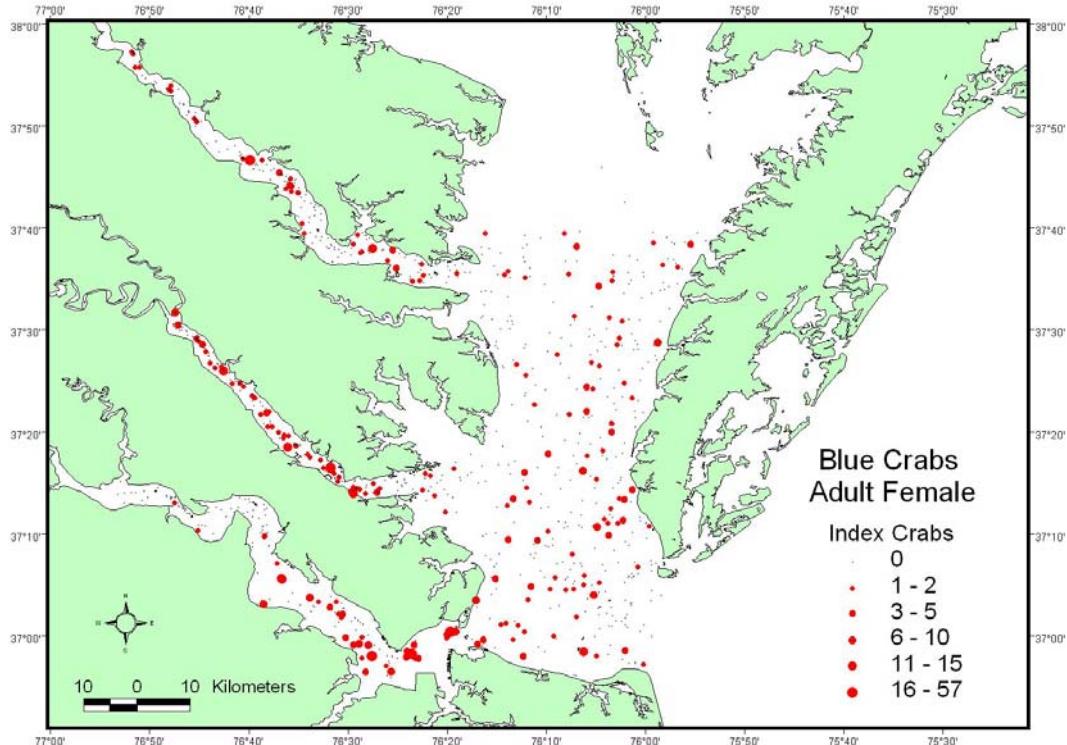

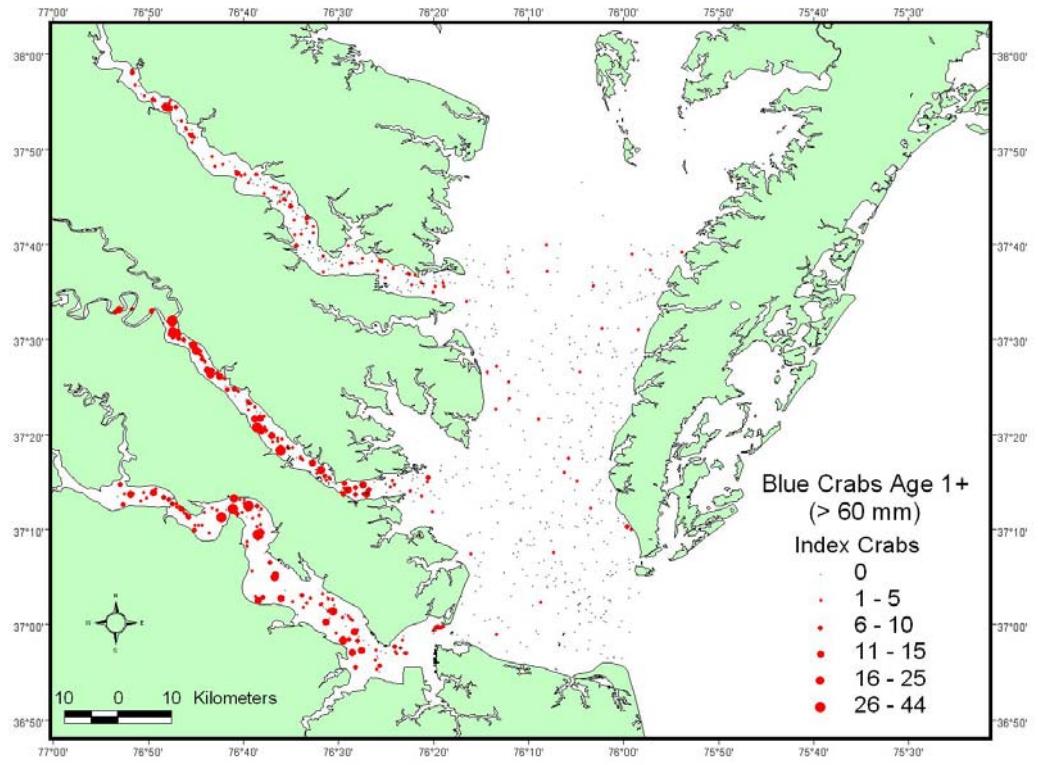

Figure 37. Distribution of Age 1+ blue crabs (top), and adult female blue crabs (bottom), from June 2005 through May 2006.

Figure 38. Size frequency of male and juvenile female blue crabs by month for June 2005 to May 2006. Index months are shown in red.

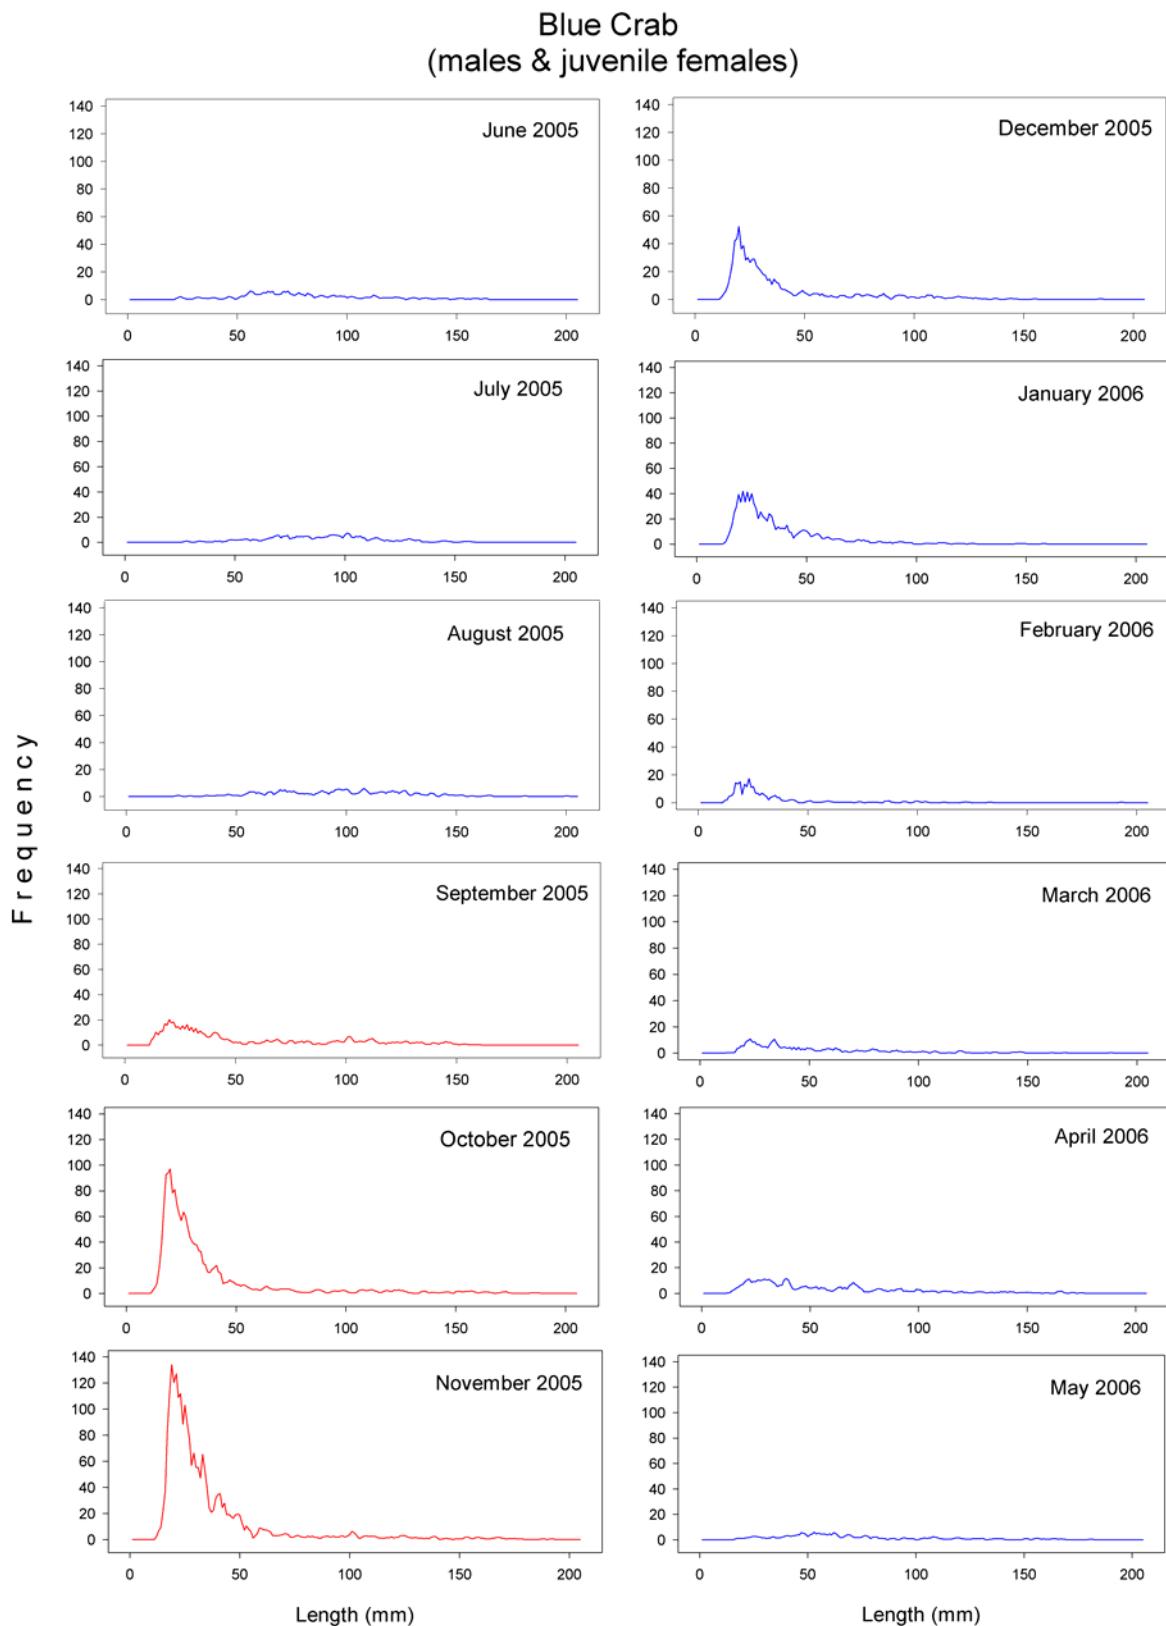

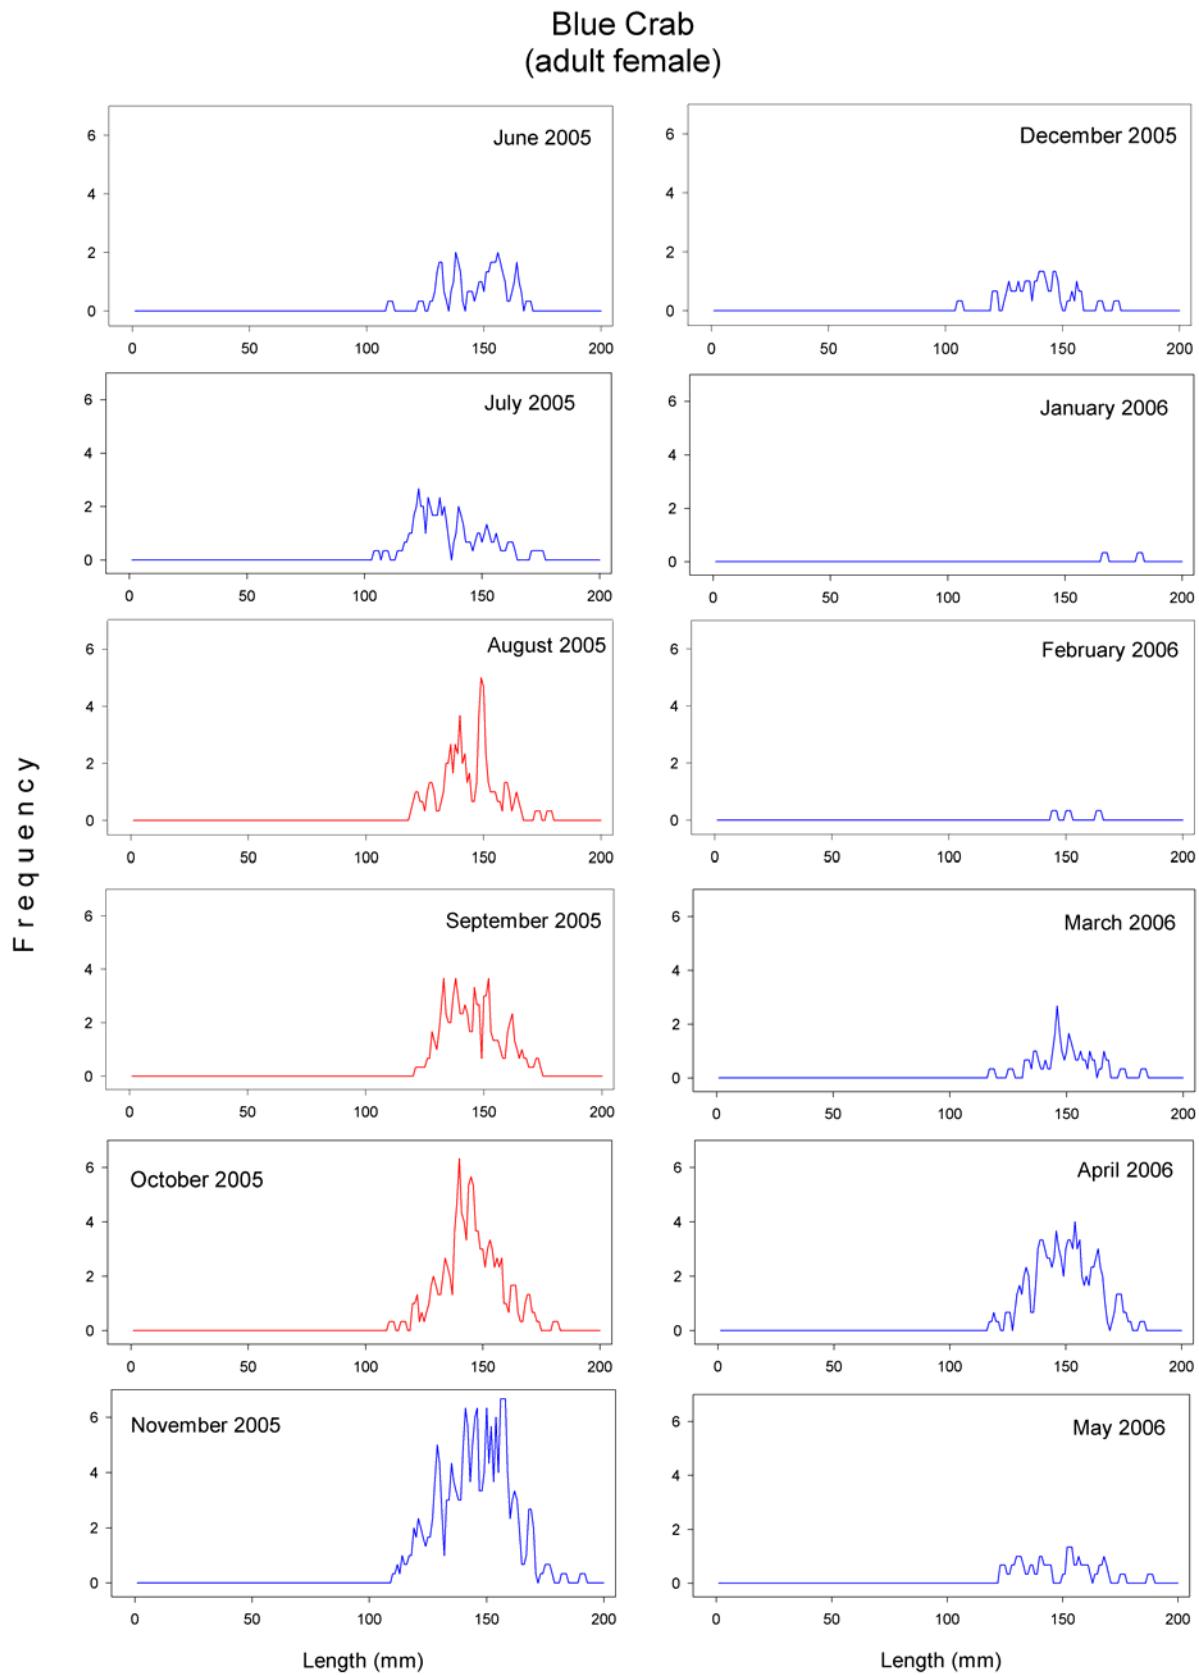

Figure 39. Size frequency of adult female blue crabs by month for June 2005 to May 2006. Index months are shown in red.

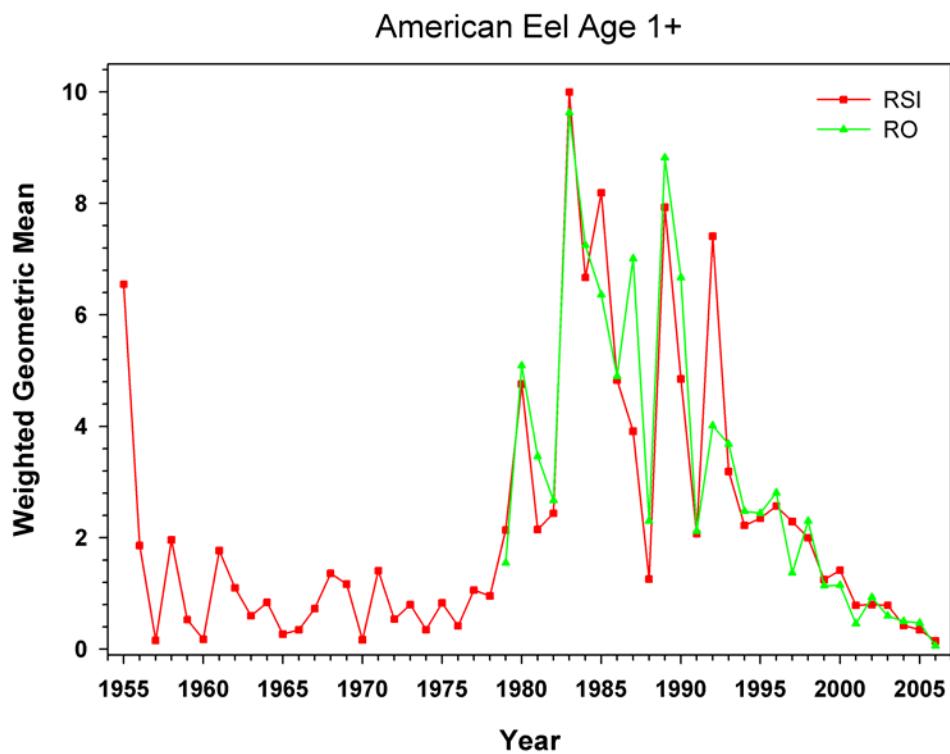

Figure 40. American eel random stratified (RSI) and fixed transect (Rivers Only-RO) indices (**top**), and distribution of American eel (all year classes combined; **bottom**) from June 2005 through May 2006.

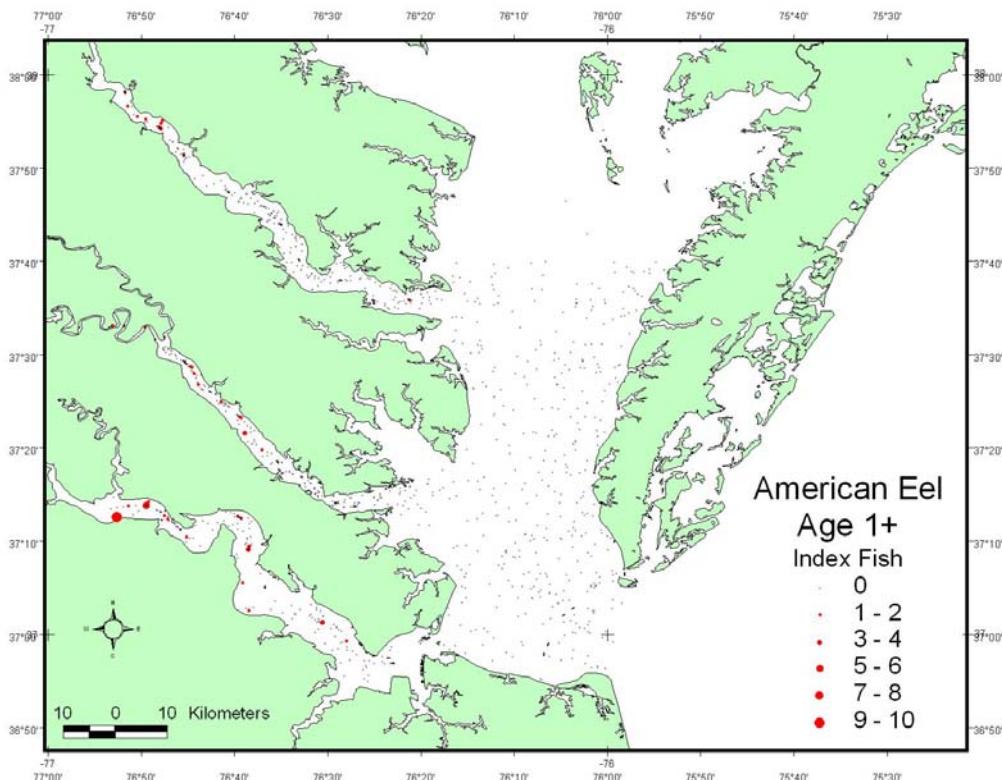

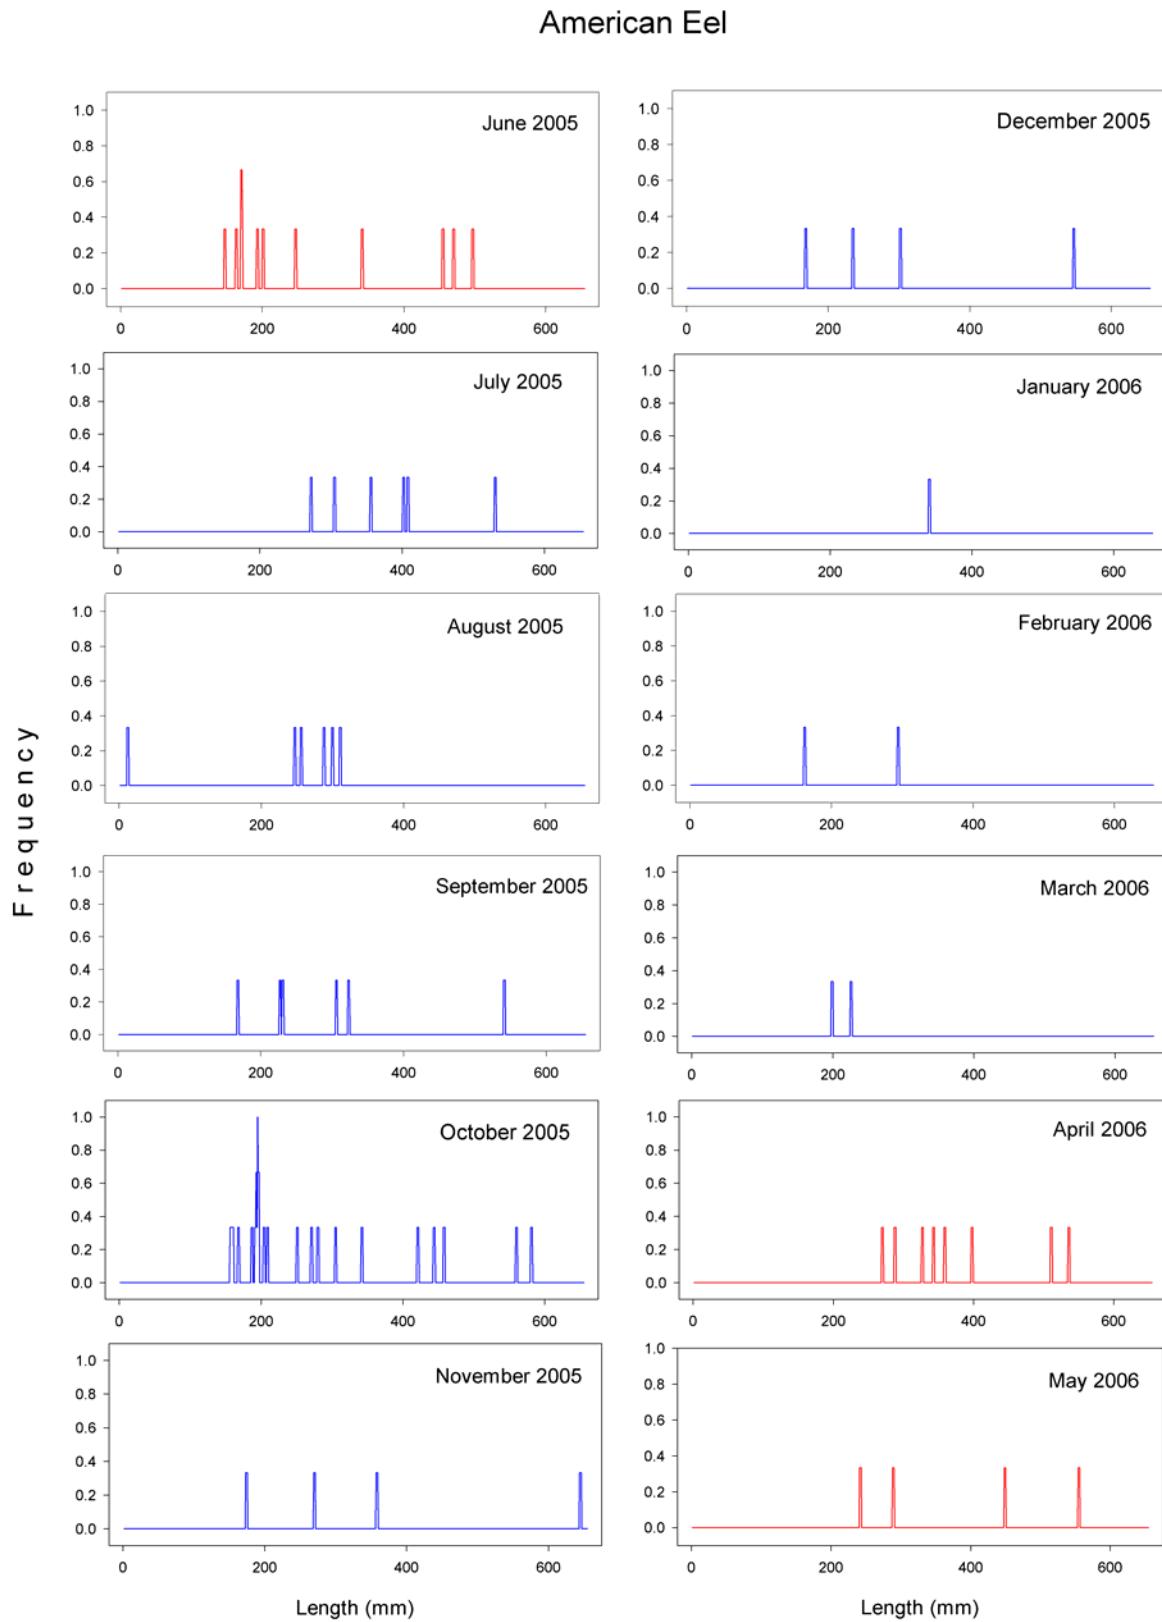

Figure 41. Size frequency of American eels by month for June 2005 to May 2006. Index months are shown in red.

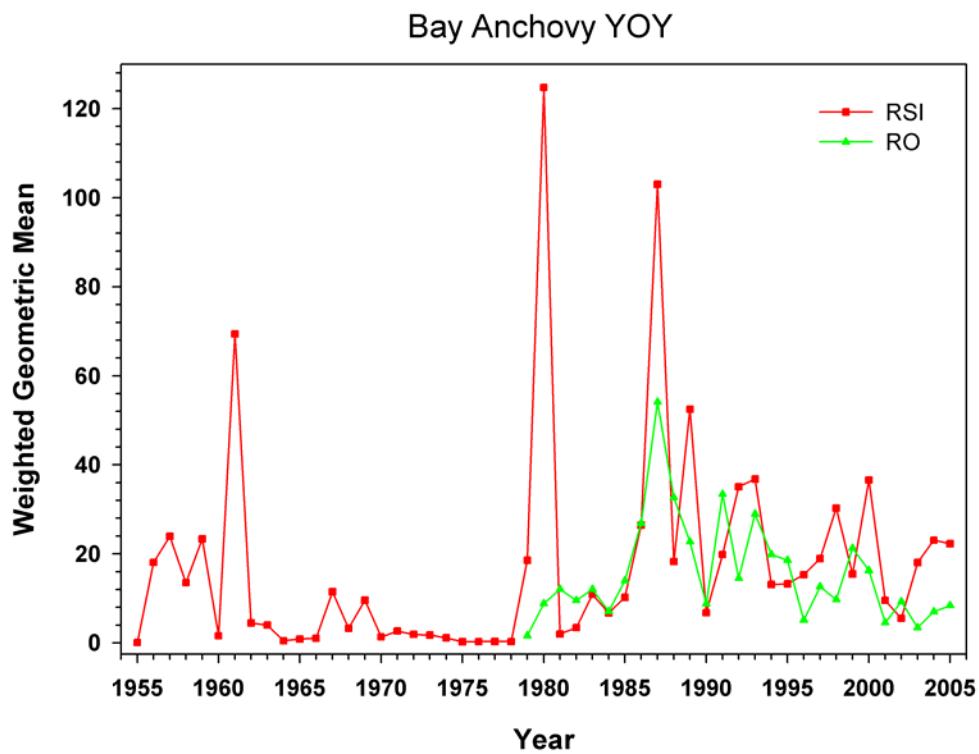

Figure 42. Bay anchovy random stratified (RSI) and fixed transect (Rivers Only-RO) indices (top), and distribution of YOY bay anchovy from June 2005 through May 2006 (bottom).

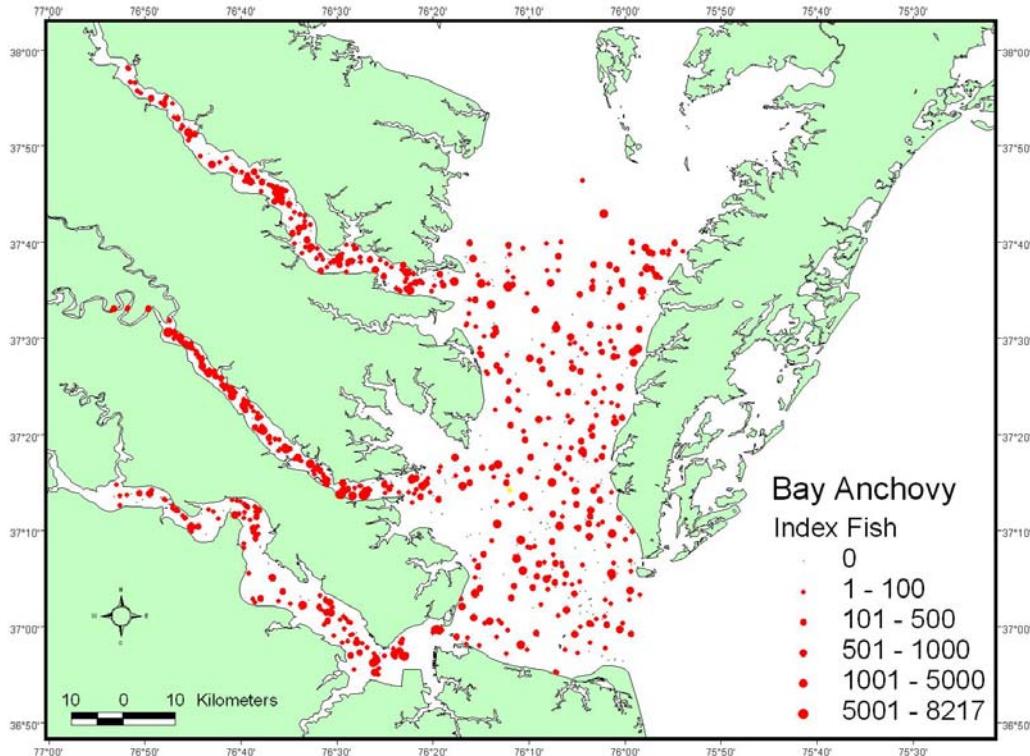

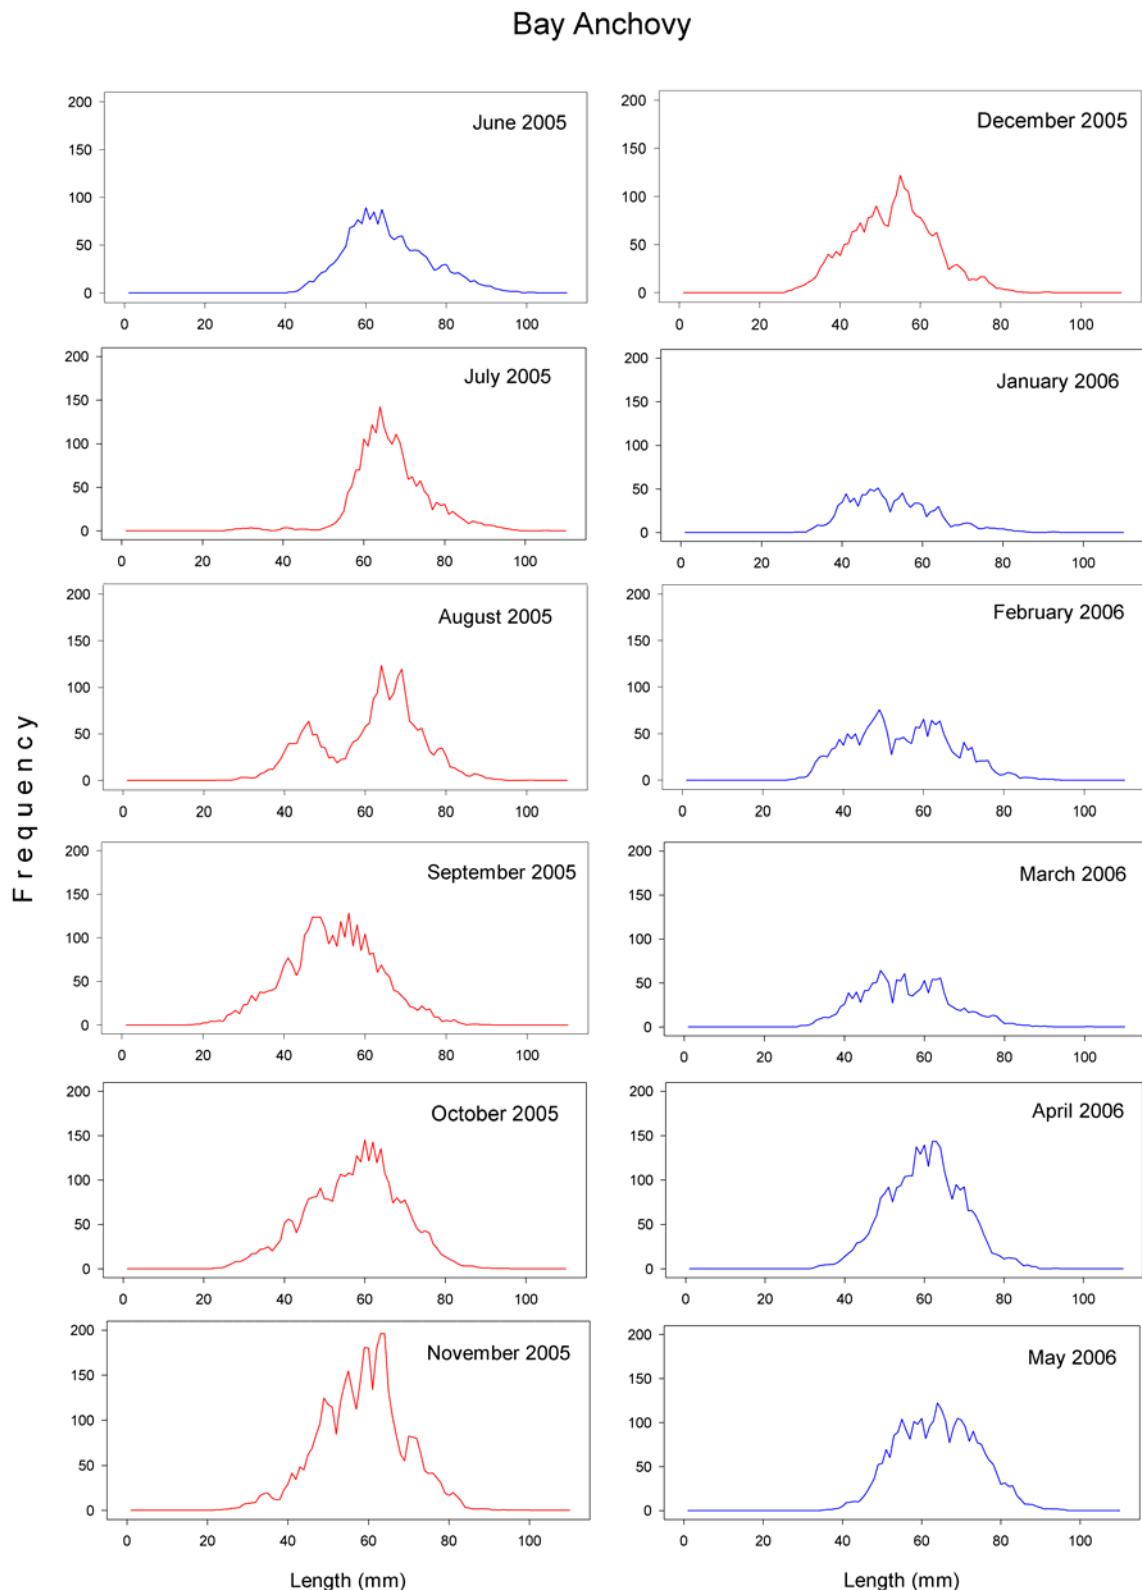

Figure 43. Size frequency of bay anchovy by month for June 2005 to May 2006. Index months are shown in red.

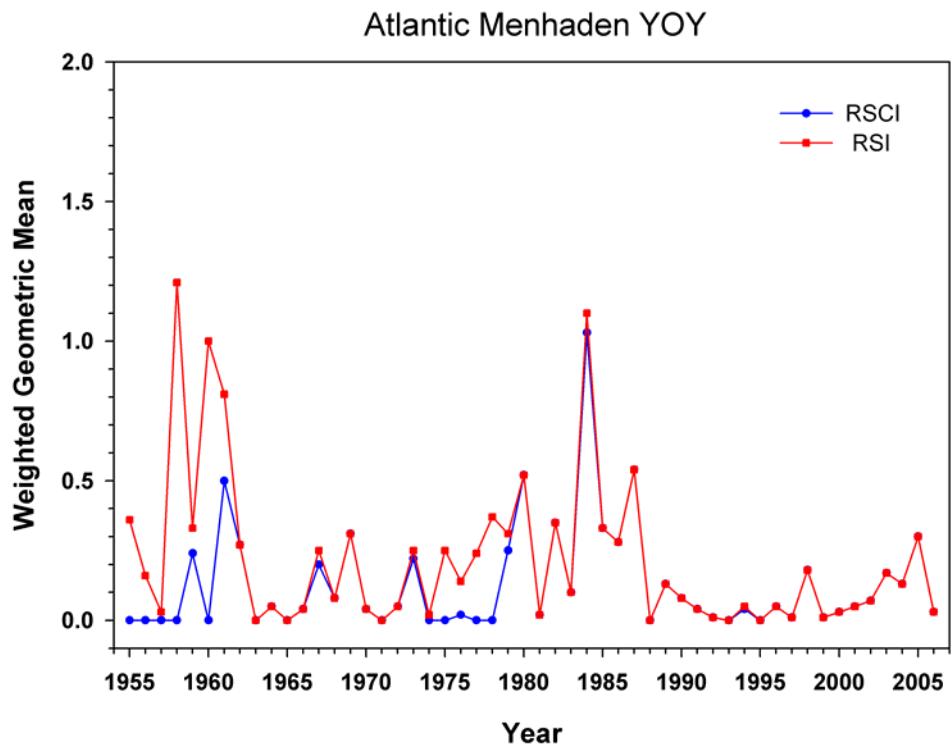

Figure 44. YOY Atlantic menhaden random stratified (RSI) and random stratified converted (RSCI) indices (**top**), and distribution of YOY Atlantic menhaden from June 2005 through May 2006 (**bottom**).

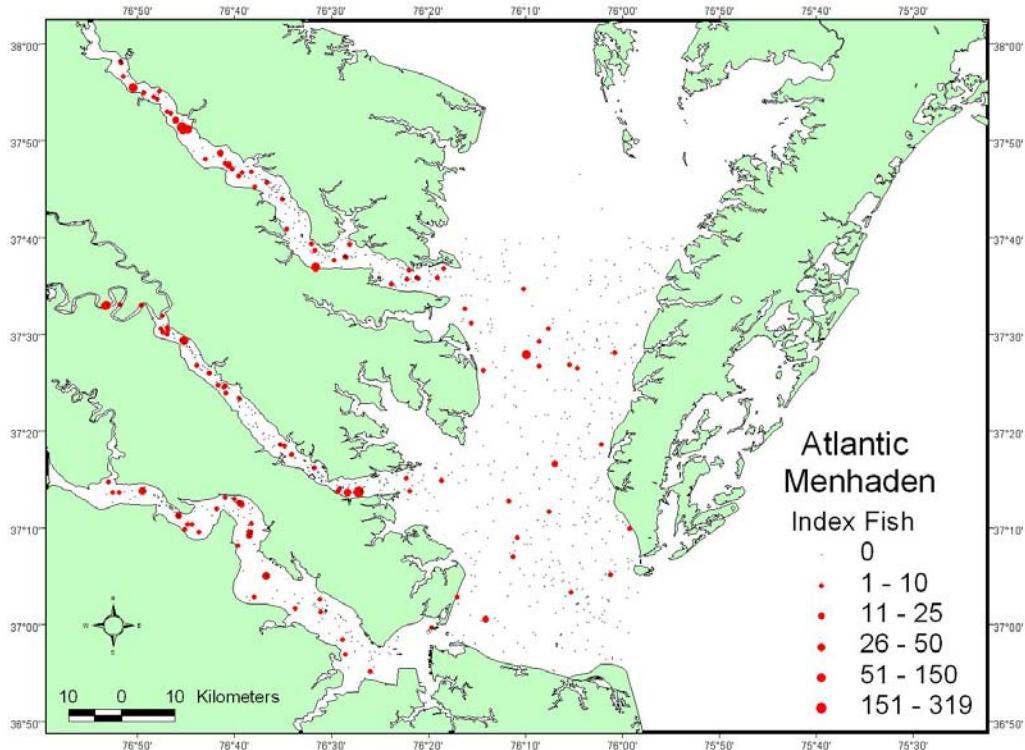

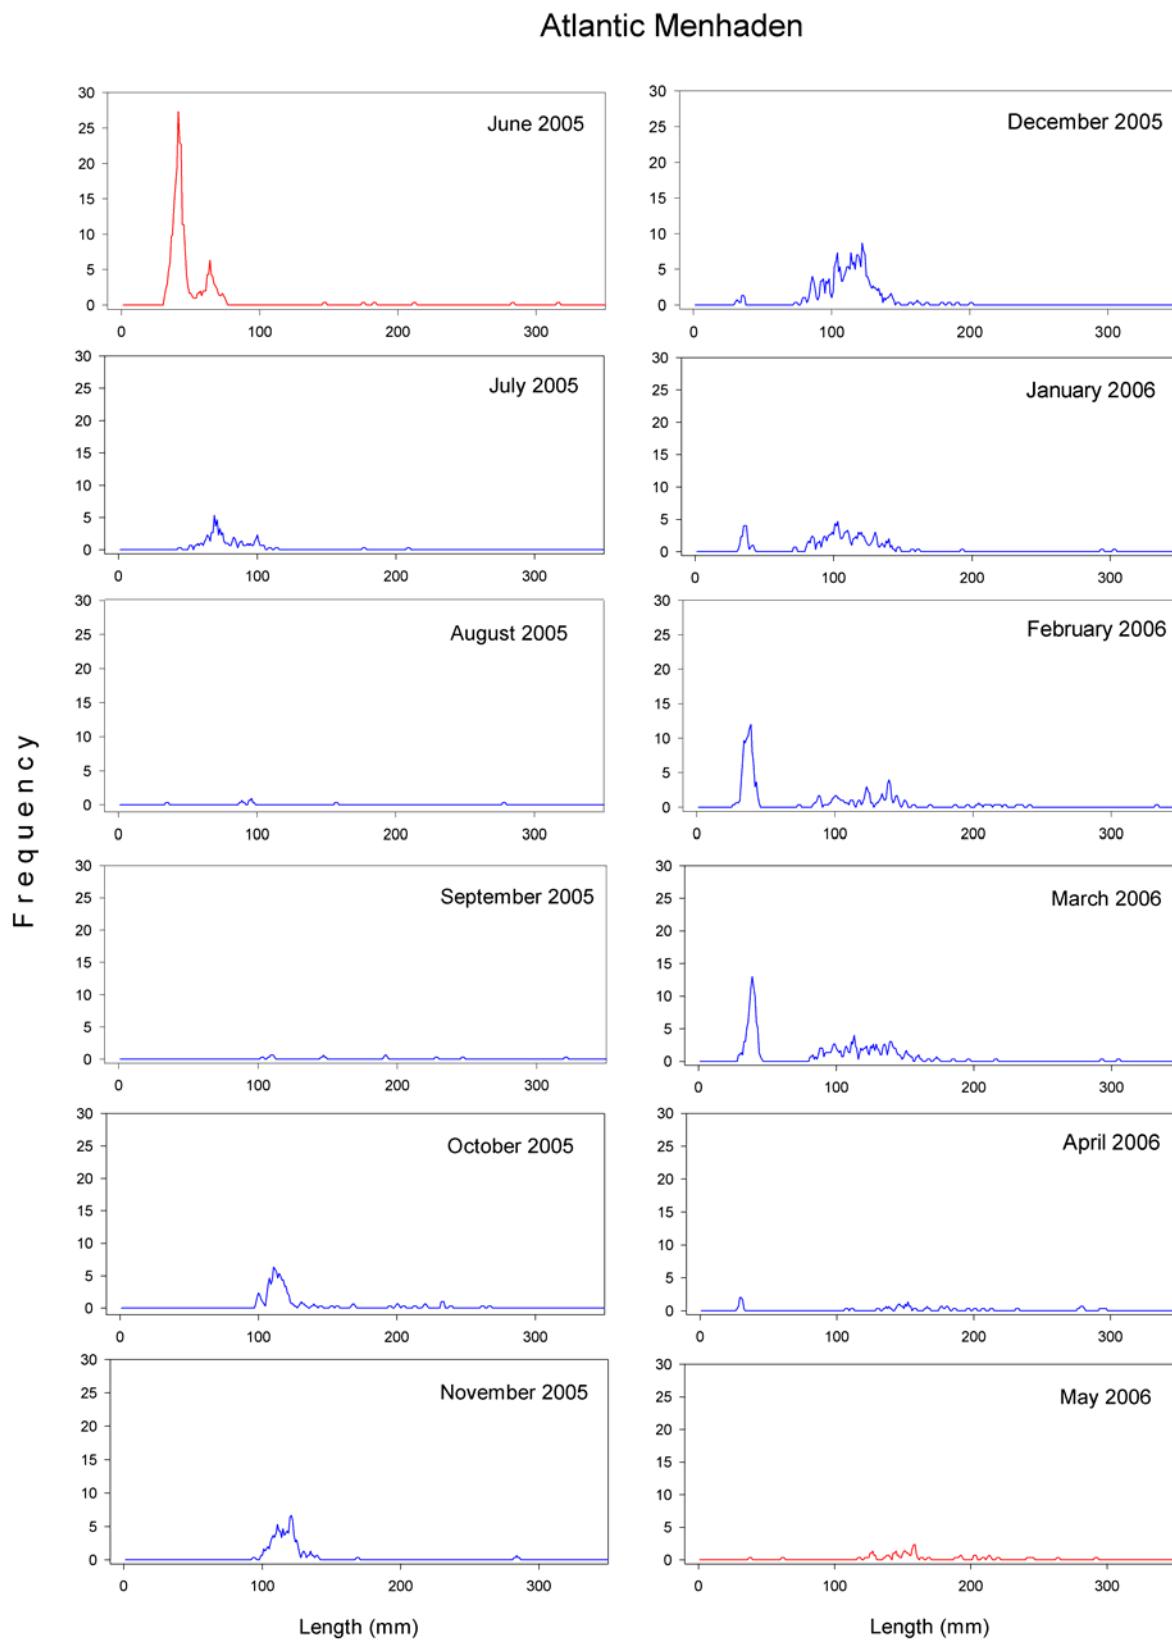

Figure 45. Size frequency of Atlantic menhaden by month for June 2005 to May 2006. Index months are shown in red.

Appendix Table 1. Listing of recent Trawl Survey advisory requests

Date	Agency	Nature of Request	Time Spent on Request (hrs)
6/1/05	VIMS Wetlands	Summer Flounder Data	0.25
6/29/05	VIMS	Sturgeon Data	0.25
7/7/05	Malcolm Pirnie, Inc.	Station JA 124 Data	1.00
